Diffusion of Gender Norms:
Evidence from Stalin's Ethnic Deportations[*]

This draft: March 2020
(First draft: June 2019)

Abstract

We study horizontal between-group cultural transmission using a unique historical setting, which combines exogenous group exposure with no control over whether and how the representatives of different groups interact. Stalin's ethnic deportations during WWII moved over 2 million people—the majority of whom were ethnic Germans and Chechens—from the Western parts of the USSR to Central Asia and Siberia. As a result, the native population of the deportation destinations was exposed to groups with drastically different gender norms. Combining historical archival data with contemporary surveys, we document that gender norms diffused from deportees to the local population, resulting in changes in attitudes and behavior. Norms of gender equality diffused more than norms of gender discrimination. Identification relies on the fact that, within subnational regions, the local population was fairly homogeneous, while deportation destinations were determined by local demands for manual labor, orthogonal to identity and skills of deportees.

Keywords: Horizontal cultural transmission, Gender norms, Deportations, Stalin

1 INTRODUCTION

The last two decades mark the emergence of a consensus in social sciences that culture is an important driver of human behavior, and is distinct from environment, institutions, or genes (Richerson and Boyd, n.d.; Spolaore and Wacziarg, 2013; Alesina and Giuliano, 2015). Cultural traits can be transferred both "vertically" across generations and "horizontally" across groups (Richerson and Boyd, n.d.; Bisin and Verdier, 2010). There is a large and growing body of empirical research in economics documenting cultural persistence and cultural barriers to social learning (e.g., Bisin and Verdier, 2010; Spolaore and Wacziarg, 2009). There is also vast anthropological evidence on the horizontal transmission of cultural traits (Henrich, 2017). In contrast, economic research on between-group cultural transmission is rather scarce and yields mixed results about whether exposure to a group with different cultural norms leads to cultural diffusion. When exposed, people may embrace new alien cultures (Clingingsmith, Khwaja and Kremer, 2009; Tuccio and Wahba, 2018) or reject them and increase identification with their own (Grosfeld, Rodnyansky and Zhuravskaya, 2013; Sakalli, 2018).

Well-identified studies of interactions between different groups use quasi-natural experiments to ensure exogenous sources of variation in exposure. Such experiments randomly assign people of different cultural backgrounds to the same locations. For example, the literature studied the random allocation of children to classes, students to dorms, migrants to social housing, and soldiers to regiments.[1] Typically, however, in many controlled experiments, representatives of different groups are incentivised to cooperate (e.g., students and soldiers are often assigned common tasks). Alternatively, they are united by a common goal, as is the case in the setting considered by Clingingsmith, Khwaja and Kremer (2009) who demonstrate a change in attitudes among Hajj participants after being exposed to representatives of other cultures during their pilgrimage. In many real settings, however, people choose freely whether to interact with members of other ethnic groups, and groups often have conflicting objectives. Even when groups coexist in close proximity, people may self-segregate and avoid contact with representatives of other groups.

Therefore, to study cultural diffusion one needs to combine an experimental setting of cultural exposure with having no control over interactions between individuals. Stalin's ethnic deportations during WWII have both of these features. We use these deportations as a historical experiment to study how gender norms, a cultural trait

---

[1]Most of these studies focus on testing the contact hypothesis (Allport, 1954) by examining the effect of group exposure on inter-group prejudice and discrimination (Boisjoly et al., 2006; Carrell, Hoekstra and West, 2015; Finseraas and Kotsadam, 2017; Scacco and Warren, 2018; Burns, Corno and Ferrara, 2019; Rao, 2019). Some test how diversity affects the provision of a common good (e.g., Algan, Hémet and Laitin, 2016). Only few, such as Burns, Corno and Ferrara (2019) and Rao (2019), also find imitation of behavior across groups.

that differed sharply across deported groups, diffused from deportees to the native population at the destination locations through social learning and imitation.

2.16 million people from several different ethnic groups, including the entire German and Chechen populations of the USSR, were deported from the Western parts of the USSR to Siberia and Central Asia between 1939 and 1944. The sole reason for their deportation was suspicion by Soviet authorities of (potential or actual) collaboration of some members of these ethnic groups with the Nazis during WWII. The largest four groups of ethnic deportees were: Soviet Germans (over 1 million of them were deported), Chechens (over 450 thousand were deported), Crimean Tatars (almost 185 thousand were deported) and Meskhetian Turks (over 75 thousand were deported). Germans and Chechens constituted over 70% of all ethnic deportees and together with Crimean Tatars and Meskhetian Turks – 84%. These deportations were indiscriminate: all members of these ethnic groups, including men, women, and children, were brought to remote locations in the eastern parts of the USSR, far from the WWII front. Unlike Gulag prisoners, they were not confined to camps and were not guarded. Deportees were free to interact with the local population. Upon arrival they typically were instructed to find accommodation among the locals and send their children to the same schools as locals. They worked in the same places as locals. However, deportees were restricted to blue-collar occupations.

Deportees were not allowed to leave their destination localities and had to report regularly to the local special police (NKVD, *People's Commissariat for Internal Affairs*) to verify their physical presence in the destination locality. This restriction was binding until the fall of the Soviet Union in 1991 for three out of four largest groups of deportees: Soviet Germans, Crimean Tatars, and Meskhetian Turks. For the rest, and notably, for the second largest group of ethnic deportees, Chechens, the restriction was lifted in 1956-1957 during the Khrushchev Thaw. The vast majority of deportees and their descendants left the deportation locations after they were allowed.

Deportee groups differed along many dimensions, such as traditional religion, education, occupation, place of origin, and gender norms. For example, before the Soviet anti-religion campaigns of the 1920s and 1930s, the vast majority of Soviet Germans identified themselves as Protestant Christians; whereas Chechens, Crimean Tatars, and Meskhetian Turks practiced Sunni Islam. Literacy rates and education levels were highest among Germans compared to other deportee groups.

We focus on one dimension of these differences: gender norms. The Soviet government tried to impose gender equality on all ethnic groups in the USSR starting with the 1917 Bolshevik revolution. Some groups resisted this policy more than others, and pre-1917 differences in gender norms among ethnic groups within the USSR were large. In the background section (below), we present anthropological evidence at the

time of the deportations and systematic evidence from a pre-deportation census, both of which indicate that: (1) Soviet Germans had the most progressive (i.e., egalitarian) attitudes toward the role of women and men in the society and in the family compared to any other large deportee group or the local population at the destination locations in Central Asia and Siberia; (2) in contrast, the most regressive gender norms among all groups were widespread among the largest Muslim group of deportees, Chechens. More generally, all groups of deportees with Protestantism as traditional religion had more progressive gender norms compared to all groups of deportees who traditionally were Sunni Muslims.[2]

In Central Asia, the majority of the local population belonged to Central Asian ethnic groups: Kazakhs, Uzbeks, Kyrgyz, Tajik, and Turkmen. Traditional gender norms of these local natives at the destination locations were similar to those of Chechen deportees (polygyny, veils for women, female illiteracy, and child marriages were widespread). However, as anthropologists have argued, these groups resisted Soviet policies of gender equality less than did Chechens. In Siberia, the local population was predominantly ethnic Russian, who had substantially more egalitarian gender norms than Muslim deportees, but did not have as long tradition of gender equality as German deportees.

We test whether gender norms transferred horizontally from deportees to the local native population. In particular, we study how gender-related attitudes and behavior of natives depend on the group composition of deportees in destination localities. The way destination localities were determined allows us to overcome potential endogeneity problems. Central authorities determined the quotas of each deportee group in every subnational-region (the first-tier administrative division within Soviet Republics) possibly depending on factors correlated with the cultural traits of the native population. In contrast, within-regions, the allocation of deportees across localities was unrelated to their culture or the culture of natives. First, within regions, the local native population was fairly homogeneous. Second, the assignment of deportees to a particular locality within regions was driven by local needs for manual labor—the main occupation of ethnic deportees at their destinations—and was orthogonal to the skills, ethnic identity, and culture of deportees.

Consistent with the historical narrative about the choice of destination locations, a large list of observables measured at deportation destinations is balanced with respect to within-region group composition of ethnic deportees. In particular, we show that the relative share of Protestant vs. Muslim deportees, conditional on the number of

---

[2]Soviet Germans constituted 96.5% of all deported Protestants. Chechens constituted 60%, Crimean Tatars 25%, and Meskhetian Turks 10% of all deported Sunni Muslims. Ethnic groups with traditional religion other than Protestantism or Sunni Islam represented less than 13% of all ethnic deportees.

ethnic deportees at the destination location and region fixed effects, is uncorrelated with demographic, economic, and geographical characteristics. In contrast, the destinations of ethnic deportations differed from the places that did not receive deportees by a number of important aspects. For example, they were closer to railroads, as deportees arrived to destination regions by rail, and were closer to Gulag camp sites, as some massive construction projects required the work of Gulag prisoners, free local workers, and deportees.

We combine historical and contemporary data for our analysis. Data on the number of deportees of each ethnicity at each destination location come from the 1951 census of all deportees conducted by NKVD (available from the Russian national archives). As outcome variables, we use attitudinal questions on gender roles and on gender-specific behavior, such as education and entrepreneurship, from the 2016 wave of the Life in Transition Survey (LiTS). We focus on respondents from the five countries that received ethnic deportees: Russia, Kazakhstan, Kyrgyzstan, Uzbekistan, and Tajikistan.[3] We also collected a number of geographical and historical characteristics for deportation destinations.

Our empirical strategy is straightforward. We compare attitudes and behavior of respondents within the same regions between localities that hosted ethnic deportations comprised mostly of Muslim deportees and localities with deportations consisting mostly of Protestant deportees. We use traditional religion of deportees as a proxy for their gender norms. To make sure that descendants of deportees are not in our sample, we only consider respondents who belong to the local native majority group: ethnic Russians in Siberia, and Kazakhs, Uzbeks, Kyrgyz, and Tajiks in Central Asia.

Figure 1 illustrates the main pattern in the data: it presents the mean difference in progressive gender attitudes and in female entrepreneurship rates between respondents from localities that hosted ethnic deportees and all respondents from the regions of these localities, by tercile of the local share of Protestants among deportees. The figure shows that progressive gender attitudes and female entrepreneurship rates are below regional averages in localities with the lowest share of Protestants among deportees and are above regional averages in localities with the highest share of Protestants among deportees.

The results of the regression analysis confirm this pattern. We find that respondents have more progressive attitudes toward the role of women in society and in the family if the ethnic deportees who lived in their locality were Protestants (equivalent to saying that they were Germans), compared to respondents from localities, in which the deportees were Muslims (mostly, Chechens). Furthermore, female entrepreneurship rates

---

[3]Turkmenistan is the only country that received ethnic deportations and is not in our sample because the LiTS survey did not cover it. Only 0.1% of all ethnic deportees were sent to Turkmenistan.

4

are significantly higher today in localities in the vicinity of Protestant deportations compared to Muslim deportations. As we find no difference in entrepreneurship rates among men between locations of Protestant vs. Muslim deportations, it is unlikely that environment rather than social norms drives the differences in female entrepreneurship rates. Importantly, we also find that mothers of respondents from localities that were the destinations of Protestant deportations (compared to mothers of respondents from localities that were the destinations of Muslim deportations) have significantly higher educational attainment, but only for cohorts that completed compulsory schooling after deportees arrived to destination localities. This evidence also suggests that our results are not driven by unobserved heterogeneity between localities within regions.

The results are also not driven by selective in- or out-migration of the local population. We use information on the place of residence of respondents' ancestors before WWII to show that the results are robust to restricting the sample to respondents whose families lived before WWII in the same region as the respondent. Furthermore, the probability of out-migration of natives from the deportation region is not related to the group composition of deportees.

Controlling for region fixed effects and the presence of an ethnic deportation in the vicinity of a respondent's locality are crucial for our identification because the group composition of deportees is expected to be unrelated to pre-existing cultural attributes of the native population only after conditioning on these covariates. Once we control for region fixed effects and the presence of an ethnic deportation, our results are robust irrespective of whether we control for a battery of geographic, climate, and historical variables (such as the size of the municipal population in 1939, average summer and winter temperature and precipitation, ruggedness, distances to the closest railroad, to Gulag camp site, to past or present capital city, and to evacuated enterprises, and the urban/rural/capital status of a location), or for the respondent's demographics and socio-economic status. To understand whether variation in unobservables could drive our results, we use tests developed by Altonji, Elder and Taber (2005) and Oster (2017). These exercises suggest that the results are unlikely to be driven by confounding factors. In our baseline specification, we correct standard errors for spatial correlation within a 150km radius following Conley (1999), and we establish robustness to alternative assumptions about variance-covariance matrix.

The magnitude of the effects is large. If we compare two respondents today, who live in the same region but in different localities, which were the destinations of ethnic deportations (of an average size), such that one locality had only Protestant deportees and the other—only Muslim deportees, we find that those female respondents who live near the site of Muslim deportations are 21 percentage points more likely to agree with the statement: *"A woman should do most of the household chores even if the husband*

5

is unemployed" and 11 percentage points more likely to agree that *"It is better for everyone involved if the man earns the money in the family"* than female respondents who live next to the site of only Protestant deportations. For male respondents, these differences are even larger: 22 and 19 percentage points, respectively. Women, who today live near locations of Protestant deportations, are 13 percentage points more likely to have tried to open their own business than their counterparts from locations of Muslim deportations. We also find a 8.7 percentage point difference in the attainment of tertiary education among women young enough to attend compulsory school after the deportees had arrived between sites of only-Protestant and only-Muslim ethnic deportations.[4]

Our paper relates to several strands of economics literature. By providing evidence on the between-group diffusion of a cultural trait, gender norms, our main contribution is to the literature on between-group cultural transmission (Clingingsmith, Khwaja and Kremer, 2009; Bisin and Verdier, 2010; Spolaore and Wacziarg, 2013; Alesina and Giuliano, 2015; Tuccio and Wahba, 2018).

Our analysis is also related to the literature on social contact (e.g., Angrist, 1995; Boisjoly et al., 2006; Carrell, Hoekstra and West, 2015; Algan, Hémet and Laitin, 2016; Chetty, Hendren and Katz, 2016; Finseraas and Kotsadam, 2017; Scacco and Warren, 2018; Burns, Corno and Ferrara, 2019; Rao, 2019). Most of the papers in this literature use (quasi-)experimental settings to estimate the effects of group exposure on a variety of outcomes, including inter-group prejudice and educational performance. In contrast to our study, however, these papers do not consider cultural traits as outcomes.

We also contribute to a growing literature on the determinants of gender roles (e.g., Goldin, 1990; Fernández, Fogli and Olivetti, 2004; Becker and Woessmann, 2008; Fernández and Fogli, 2009; Fogli and Veldkamp, 2011; Alesina, Giuliano and Nunn, 2013; Giavazzi, Schiantarelli and Serafinelli, 2013; Fernández, 2013; Hiller, 2014; Giuliano, 2017; Campa and Serafinelli, 2018; Lippmann, Georgieff and Senik, forthcoming). In particular, our work is related to the literature on peer effects in gender norms (Maurin and Moschion, 2009; Nicoletti, Salvanes and Tominey, 2018; Schmitz and Weinhardt, 2019; Olivetti, Patacchini and Zenou, forthcoming). Schmitz and Weinhardt (2019), for instance, show that West Germans in localities exposed to higher levels of in-migration of East Germans after the unification of Germany exhibit more progressive gender norms, using the distance to the border between East and West Germany as a source of variation. They interpret the results as evidence of cultural transmission from East Germans to West Germans. Our paper focuses on horizontal transmission of gender

---

[4]We also find evidence consistent with the hypothesis that higher cultural distance between deportees and the local population resulted in a larger adjustment of norms among the locals. This evidence, however, is not very robust.

Electronic copy available at: https://ssrn.com/abstract=3417682

norms between different ethnic groups and uses forced migration for identification.

Our work is also related to the literature on peer effects in education (surveyed in Epple and Romano, 2011; Sacerdote, 2011, 2014). Algan et al. (2018) document a convergence in the political views of students who formed friendships after being randomly allocated into classes during a university initiation program. A key difference between our analysis and any estimates of the effects of the random allocation of students to classes is that interactions between students are encouraged and regulated, whereas this was not the case for ethnic deportees and the native population in our setting.[5]

The paper proceeds as follows. In Section 2, we provide historical background. In particular, we present details on how the destinations of ethnic deportations were determined and analyse the differences in gender norms among deportee groups and between deportees and the local population at the destination locations. Section 3 presents data sources. In Section 4, we describe the empirical strategy and discuss the main identification assumptions. Section 5 reports the results. In Section 6, we explore heterogeneity with respect to cultural distance. In Section 7, we test for and reject alternative explanations related to selective in- and out-migration of locals. Section 8 concludes.

2 Historical Background

2.1 Ethnic deportations during WWII

The timing of deportations.—Ethnic deportations were decided by decrees issued by Soviet authorities. The official goal of the ethnic deportations was the purge of "anti-Soviet, alien, and suspicious elements" as stated by Lavrentiy Beria, the head of NKVD at that time (Polian, 2004, p. 139). Ethnic deportations took place in three waves. First, in 1939-1941, several selective deportations took place from the annexed territories in Poland, the Baltics, and Romania, with the goal of suppressing local resistance against the Soviet occupation, following the Ribbentrop-Molotov Pact. The second wave took place in 1941-1942, after the Nazis and Soviets became enemies. The deportations of this wave were called "preventive," i.e., they claimed to prevent the deported groups from collaborating with the Nazis. These deportations were in-

---

[5]We also contribute to the literature on the consequences of Stalin's punitive policies. For instance, Toews and Vezina (2019) and Kapelko and Markevich (2014) study the long term effects of Gulag camps. Levkin (2016) studies the effect of Stalin's ethnic deportations on distrust in central authority. He compares places that were the destinations of ethnic deportations with places that were not destinations of ethnic deportations. In contrast, we explore an exogenous variation in the ethnic composition of deportations focusing only on those places that were the destinations of ethnic deportations. Becker et al. (forthcoming) estimate the effect of forced migration on the educational attainment of descendants of forced migrants.

7

discriminate, i.e., all Soviet citizens, including women and children, that belonged to the suspected ethnic groups were deported. The largest deported group during these years was the Soviet Germans. The third wave took place in 1943-1944. It was so-called "retributive," i.e., it was a punishment for the actions of a few individuals from these groups who actually collaborated with the Nazis. This deportation wave included Chechens, Crimean Tatars, and Meskhetian Turks. The deportations of the third wave were also indiscriminate. The deportations happened very rapidly so that, in many cases, there were only few days between the decree against a certain ethnic group and their actual deportation. There was no selection at the origin: practically all representatives of the groups destined for deportation were actually deported. People who tried to resist were shot (Nekrich, 1978 and Polian, 2004, pp. 147, 151). Figure A1 in the online appendix presents photos of Chechen and German deportees.

The destination locations.—A historian of ethnic deportations, J. Otto Pohl, describes the purpose of the deportations as follows: *"it [the deportation] sought to use the deportees as a caste of helot labourers to provide a captive workforce to develop the economy of Kazakhstan, Central Asia, Siberia and other remote areas of the USSR. To these ends it imposed a special legal status upon the exiles aimed at excluding them from mainstream Soviet society while at the same time integrating them into the local economy as a source of menial labour* (Pohl, 1999, p. 13).

For each ethnic deportation, NKVD in Moscow issued a directive listing the regions of destination (i.e., the *oblasts*, the first administrative division within Soviet Republics) together with quotas of deportees assigned to each region. Typically deportees were transported to the train stations on horse-drawn carriages or trucks and then by rail to the main train station of the destination region.

Historians describe that the localities where deportees ended up within the assigned region were decided only upon arrival to the destination region (Koustova, 2015; Blum and Koustova, 2018a,b). The local authorities, such as the heads of the *sovkhoz* and *kolkhoz*, the state-owned and collective farms, and the administration of local state-owned enterprises came to the main regional town to choose deportee families to work for them in their locality within the region. Families, for the most part, were left intact. The representatives of local administrations were primarily interested in recruiting young and healthy adults capable of carrying out manual labor, in what had some resemblance to a slave market. Apart from the local demand for manual labor, there were also restrictions imposed by central authorities on employing deportees in non-manual occupations.[6] Other characteristics of deportees, unrelated to their physical

---

[6]For example, Mukhina (2005) writes about such restrictions on German deportees: *"[There] were numerous orders which did not allow the use of labour of ethnic Germans for anything except the heaviest work, most often meaning timber felling and loading and unloading cargo of freight wagons. Special prohibitions had been issued against the use of Germans on lighter jobs in sovkhozy, offices or*

strength, such as ethnicity, religion or cultural background, did not play a role in their allocation to their final destinations within the assigned regions. The reason for this was that within regions the local native population was fairly homogeneous and natives in different localities had similar preferences with regard to accepting different deportee groups.

Figure 2 in the main text and Figures A2 and A3 in the online appendix present maps of the destinations of ethnic deportations and their group composition at those destinations. Table A1 in the online appendix presents the total number of ethnic deportees by religion, ethnic group, and Soviet Republic of destination in 1951.[7]

Life at destination.—The deportees constituted a new category of Soviet subjects, so-called Special Settlers (*spetsposelentsy*), who had a status "somewhere between being a citizen and a prisoner" (Blum, 2015). Once at their final destination, deportees were given work, usually on the same sites as the local population. Depending on the number of arriving deportees, they were either instructed to find accommodation to rent from the locals or to build their own (temporary) shacks. They were not allowed to leave from the assigned settlement and had to report frequently (in the beginning, as often as every three days) to the local branch of the NKVD apparatus as a check of their physical presence. Attempts to flee were severely punished (Zemskov, 2003).

In sharp contrast to Gulag camp prisoners, deportees were not guarded and were not put behind bars. They were free to move in the vicinity of their assigned settlements and could interact freely with the local population. As entire families (men, women, and children) were deported, deportee children were sent to local schools together with the children of local natives. The language of instruction was of the local majority, the deportees were not allowed to set up schools in their own languages (Pohl, 2000).

The return.—Different groups of ethnic deportees were allowed to leave the deportation destinations at different points in time between 1956 (as a result of Khrushchev's Thaw) and 1991 (as a result of the fall of the Soviet Union). The timing and terms of the "pardon" varied between different ethnic groups of deportees. Chechens were rehabilitated during Khrushchev's Thaw with respect to their civil rights and administrative status, and their pre-deportation homelands were returned to them, albeit only partially (Polian, 2004, p. 197).[8] Deportees rehabilitated during Khrushchev's Thaw progressively left their destination locations during the 1960s. In contrast, Germans,

---

in the service sector" (p. 740).

[7]These numbers are a poor indication of how many people were deported from their homelands, as the death toll during the journey to the destination places and shortly after arrival to the destinations was very high (Polian, 2004). There is also no account of how many children were born to deportees at their destinations. In contrast, these data are better suited to analyze exposure of the local native population to deportees as the mortality rates among deportees declined by the end of the war.

[8]A number of less numerous deportee groups, such as Kalmyks, Ingush, Karachais, and Balkars, were also rehabilitated (at least formally).

Electronic copy available at: https://ssrn.com/abstract=3417682

Crimean Tatars, and Meskhetian Turks, even though acquitted of the "crime" charges in 1964, were never fully "pardoned." Their pre-deportation homelands were not returned to them, and they were not allowed to leave deportation locations. While they no longer had a duty to report to the local security apparatus every third day in the 1960s, they continued to be obliged to report their presence in the deportation location once a year. A number of key restrictions on these deportees remained intact until the fall of the Soviet Union (Polian, 2004; Blum and Koustova, 2018a). Almost all Germans, Crimean Tatars, and Meskhetian Turks left their deportation settlements after the disintegration of the Soviet Union. Germans moved to Germany (as they were given German passports), Meskhetian Turks moved to Georgia, Azerbaijan, Turkey, and Russia, whereas Crimean Tatars mostly moved back to Crimea (Polian, 2004).

2.2   Gender norms among deportees and the native population

At the time of ethnic deportations, there were no quantitative studies of gender norms of ethnic or religious groups. However, there is abundant anecdotal evidence from that period collected by Soviet anthropologists. We summarize their findings in this subsection and present systematic quantitative evidence about the differences in gender norms between deportee groups and local native populations at deportation destinations before deportations took place. All pieces of evidence strongly suggest the following two conclusions. First, gender norms were substantially less egalitarian among Chechen deportees than among Soviet Germans; the same is true about the comparison between all Muslim and all Protestant deportees. Second, gender norms of the local native populations at the deportation destinations, i.e., Russians in Siberia and the local native Muslim population of Central Asian Soviet Republics, were less regressive than gender norms of Chechen deportees and more regressive than gender norms of German deportees.[9]

Official Soviet policy.—Gender equality was the official policy of the USSR. Proclaimed part of the Soviet ideology, it encompassed the spheres of education, work and family. Polygamy, child marriage, and wearing the veil were forbidden throughout the USSR. Campaigns for "the liquidation of illiteracy" (*Likbez*) of the 1920s and 1930s targeted equally men and women. Boys and girls had the same schooling obligations (e.g., Clark, 1995).

Atheism, just as gender equality, was proclaimed one of the ideological goals of the revolution. Initially, the Soviet state allowed some religious freedom for Muslims in contrast to Orthodox Christians and Protestants (as the state was not able to cope with resistances on several fronts), but this policy was overturned in 1927. At this point,

---

[9]Gender norms of ethnic Russians were closer to those of Soviet Germans, whereas gender norms of Central Asians were closer to those of Chechens.

Electronic copy available at: https://ssrn.com/abstract=3417682

all religious expression was officially forbidden until 1941, and the brutal anti-religious campaigns of the 1930s cracked down on all religious denominations (Pospielovsky, 1988).

Soviet ideological goals, however, were not equally enforced everywhere. The differences in resistance to forced gender equality and forced secularization were stark among different ethnic groups of the USSR.

Anthropological and historical evidence.—Before the revolution, female veils, polygamy, and arranged marriages of female children were common practices among the Muslim population in the North Caucasus (the origin of Chechen deportees) and in Central Asia (the destination of 58% of all ethnic deportees). In contrast, such practices were practically absent among non-Muslim population of the Russian Empire, particularly, among ethnic Russians and Germans. After the revolution, the official campaigns of female emancipation were opposed by the population both in the North Caucasus and in Central Asia. Following traditional norms proclaimed illegal by the Soviet state was considered an act of resistance against the Russian-Soviet colonizers (Northrop, 2004).[10]

Historians and anthropologists argue that, during and after WWII, deported groups, and in particular Chechens, resisted Soviet policies of female emancipation and secularization more than the local Muslim population at the deportation destinations in Central Asia. More generally, *the Chechens demonstrated a propensity for insubordination during deportations*" (e.g., Pohl, 2008). Being deported on the basis of ethnicity strengthened the ethnic identity of deportees and reinforced beliefs and practices that the Soviet state tried to eradicate. For instance, adherence to Sufism increased among Chechens during the time of deportation *"possibly to demonstrate protest against deportation and to ensure group solidarity"* (Ro'i, 2000, p. 407). Ethnic deportees from the North Caucasus observed Ramadan more strictly and celebrated Muslim festivals more actively compared to the native population (Ro'i, 2000, p. 408). Ro'i (2000) documents that *"Chechen adults were 'believers,' some of them to the point of fanaticism, and there was evidence that both Chechens... were far more religiously observant than most of the indigenous inhabitants in their areas of 're-settlement'."*

Polygyny remained common among Chechens during the time of deportations (in 1950s and 60s) and even after they returned to the North Caucasus from the deportation destinations (Ro'i, 2000, p. 539). Child marriages among Chechen deportees

---

[10]Nekrich (1978) reports sixty-nine acts of violent resistance against the imposition of new Soviet norms in 1931-1933. Traditional governance structures of the North Caucasus continued to play an important role for a long time after the revolution. Ro'i (2000) reports that some religious Muslim sects within the Chechen population were powerful enough to reject *kolkhoz* directors nominated by the local Communist party administration (*raikom*) and appoint their own nominees (p. 407). Everyday disputes were often resolved in accordance with Sharia law.

precluded girls from going to school: *"In one village, out of seventy-five girls who should have been in school in the fourth to the seventh grade, only four attended school"* (Ro'i, 2000, p. 541).

Soviet Germans were at the other end of the spectrum of gender norms among deported ethnic groups. They were the descendants of Germans, who immigrated to Russia in the late 18th century and settled mostly in the Volga region on the invitation of Catherine the Great.[11] In the Russian empire, Germans were granted unprecedented freedoms. Their culture and religion were tolerated, and they were exempt from military service and serfdom (Miller, 1987). According to the 1897 Imperial Census, 81% of Volga Germans were Protestants. Historians point out that Volga Germans instituted schools for girls as early as the 18th century (Wiens, 1997; Dietz, 2005).

After the revolution, Volga Germans continued to enjoy a special degree of autonomy, which since 1924, took the form of their own administrative region, the Volga German Autonomous Soviet Socialist Republic. Soviet Germans considered themselves the carriers of the culture of their ancestors and tried to preserve their religion, mother tongue, and folklore traditions during the first decades of the USSR, which also meant that gender equality and the level of female education were exceptionally high among this group.

After the end of the Civil War, ethnic Russians adhered to Soviet policies, including those promoting the emancipation and education of women, without much resistance. Before the revolution, gender discrimination and female illiteracy were widespread among Russians, particularly in rural areas; and Russia was predominantly rural before Stalin's industrialization. The first two decades of Soviet rule marked great progress, both in education overall and in closing the literacy gap between Russian men and women. By 1939, literacy rates among women in the Russian Soviet Federative Socialist Republic (RSFSR) reached 54% in rural areas and 73% in urban areas (the corresponding figures for male literacy in 1939 were 70% and 81%, respectively).

Evidence from the 1897 Russian empire census.—In the 1897 Russian empire census, literacy rates are available by gender, native language, province, and rural/urban status. Using these data, we compare literacy rates among men and women in 1897 for the two largest subsequently-deported ethnic groups—Germans and Chechens—and the groups that constituted the native populations at the destinations of deportations—Russians (in Siberia) and Central Asians (in Central Asia). Figure 3 presents this comparison separately in rural areas, where most of the population lived, and in urban areas. Both in rural and urban areas, Germans, on average, were more literate and the difference in literacy between men and women was substantially smaller among Germans compared to Russians, Chechens, and Central Asians. Chechens and

---

[11]Most Germans who came to the Russian empire were from the Hesse and Palatinate regions.

Central Asians had comparable literacy levels for both genders. Russians of both genders were substantially more literate than Chechen or Central Asian, but the absolute difference in literacy between men and women was not much smaller for Russians than for the two considered Muslim groups. As mentioned above, this changed during the first two decades of the Soviet rule, with the organization of the "liquidation of illiteracy" campaigns throughout the Soviet Union, as these campaigns saw less resistance in Russia than in North Caucasus or in Central Asia.

In Table A2 in the online appendix, we consider province-level data on literacy by gender and ethnic group in 1897 and show that the differences in the overall gender gaps in literacy among the four ethnic groups in 1897, presented in Figure 3, are statistically significant. In Figure A4 in the online appendix, we verify that the smaller gender gap in literacy among Germans was not a mere function of the level of education. The figure shows that the gender gap, on average, did not close (and, if anything, increased) with literacy level across Russian empire provinces for all considered ethnicities, suggesting that it is cultural norms that explain the low gender gap in literacy among Germans.

To sum up, in 1897, Germans had the lowest and Chechens had the highest gender gap in literacy among the four considered groups.

3   Data

In this section, we describe all datasets used in the analysis and present the spatial variation in the data.

3.1   Data sources and variable definitions

Ethnic deportations.—Our main treatment variable comes from a dataset on the destinations of ethnic deportations from declassified archives in the State Archive of the Russian Federation (GARF) in Moscow.[12] The data represent a 1951 snapshot of the entire surviving deportee population at destination locations originally recorded by NKVD. The dataset contains the locations and the number of deportees by ethnic group. 1131 municipalities (Soviet districts, called *rayons*) across 59 regions hosted ethnic deportations. The dataset also contains information on nonethnic deportees: *kulaks* (wealthy farmers expropriated during the collectivization), "bandits," and "anti-Soviet elements," all of whom were deported before WWII. In our analysis, we control for these nonethnic deportations.

Figure A2 in the online appendix presents the destinations of ethnic and nonethnic deportees in the data. Many of these locations hosted few deportees, however. To account for the number of deportees at destination, in Figure 2, we present the density

---

[12]These data were collected by Alain Blum.

of ethnic deportees per grid cell area. It is evident from this figure that the vast majority of ethnic deportees were brought to eastern Siberia and Central Asia. Figure A3 zooms into the geographical area with the most sizable ethnic deportations and shows the size and composition of ethnic deportations by traditional religion of the deported ethnic group for all ethnic deportees. This map also presents regional boundaries, which are important for our analysis because, for identification, we rely on within-region variation in the composition of ethnic deportations.

We perform two checks on the deportations data using archival information about the number of ethnic deportees at destination in 1946, originally collected by NKVD (and digitized by us) and the 1970 Soviet census (from http://www.demoscope.ru/, accessed on March 23, 2020), both available at the regional level. These reality checks reveal a strong persistence in the spatial distribution of deported groups across deportation destinations over a quarter of the century. The results are presented in Figure A5 in the online appendix. Panel A compares the numbers of ethnic deportees recorded by NKVD in 1951 and 1946 by destination region. In Panel B, we compare the numbers of deportees in 1951 by destination region with the number of people who belong to the deported ethnicities in the same region according to the 1970 USSR census, excluding Chechens, the majority of whom left the deportation destinations before 1970. There is a strong positive correlation between the numbers of Protestant and Muslim deportees by region over time.

Life in Transition Survey.—Our outcome variables come from the Life in Transition Survey (LiTS) conducted by the European Bank for Reconstruction and Development in the fall of 2015 and the spring of 2016.[13] The survey covered 34 countries in Eastern and Central Europe and Central Asia. We focus on five countries included in LiTS that were the destinations of ethnic deportations during WWII: Russia, Kazakhstan, Uzbekistan, Kyrgyzstan, and Tajikistan. About 1500 households were sampled at random from 75 primary sampling units (PSUs) in each of these countries. An adult member of each households was chosen at random to answer a broad set of attitudinal questions, as well as questions about his or her socio-economic and demographic characteristics.

Our main focus is on the questions about attitudes toward gender roles in society and in the family.[14] In particular, we measure gender attitudes using responses to the following three questions: (a) *"A woman should do most of the household chores even if the husband is unemployed. Do you agree?"*; (b) *"It is better for everyone if the man earns the money and the woman takes care of home. Do you agree?"*; (c) *"Men make*

---

[13]The description of the survey, its methodology, and summary statistics can be found at: https://www.ebrd.com/publications/life-in-transition-iii (accessed on April 22, 2019).

[14]These questions were asked in the 2016 wave of LiTS for the first time.

14

better political leaders than women do. Do you agree?". The response options were on a 4-point-Likert scale. We create dummies coding "strongly disagree" and "disagree" as 1, and "strongly agree" and "agree" as 0, so that higher values mean more progressive attitudes. As there was no response option "neither agree, nor disagree," our coding encompasses all response options. We also aggregate the three dummies into a single measure by calculating their first principal component, in which all factor loadings turn out to be positive, and by normalizing the resulting measure to be between 0 and 1.

To test whether self-reported gender attitudes translate into behavior, we also consider the following behavioral characteristics: dummies indicating whether female respondents tried to start a business, whether respondents of both genders take part in a women's rights advocacy association, and whether respondents' mothers obtained tertiary education. The information on the educational attainment of respondent's mothers allows us to test for pre-treatment differences between treated localities. We use mothers' education as an outcome separately for cohorts of respondents' mothers who finished compulsory schooling before and after deportees arrived to their localities. As there is no age of mothers in LiTS, we predict the birth year of the mother of each respondent using respondent's age and aggregate data on the average age of women at the time of birth of each of their children by women's birth cohort in the USSR. These data come from The Human Fertility Collection (HFC).[15]

Historical variables.—There is less information about the number of locals at the destination locations of ethnic deportations than about the deportees themselves. We construct proxies for the demographic characteristics of the local native population using the 1939 USSR census, which gives population characteristics at the municipality (1939 rayon) level.[16] Importantly, this is a noisy proxy for two reasons. First, Soviet Union lost over 15% of its population in WWII. Second, we do not know 1939 population density because there is no municipality-level map of the USSR as of 1939. We matched the 1939 population data to the localities of LiTS respondents using district names.

There is more population data from 1897 Russian empire census than from 1939 Soviet census. In addition to province-level data, which we used in Figure 3, data from the 1897 Russian empire census were published at a more disaggregated county (*uezd*) level. Castañeda Dower and Markevich (2020) digitized these data for Russia and we digitized them for Central Asia.[17] In particular, we collected the following

---

[15]These data are available at https://www.fertilitydata.org/cgi-bin/country.php?code=rus (accessed on April 24, 2019).

[16]These data are made available by Demoscope (http://www.demoscope.ru/, accessed on March 23, 2020).

[17]We use digital map from Castañeda Dower and Markevich (2018) to match the 1897 population statistics with the rest of the data.

variables: population density, urbanization, religious composition, the shares of Russian and German minorities, the shares of those working in agriculture, in industry, and in services and trade, and the share of the population employed in white collar jobs. In addition, for all counties in the four Central Asian states covered by LiTS data, we also collected data on the share of literate women. We use the 1897 variables to check the pre-deportations balance in our main treatment variable.

To check for potential confounding factors, we use data on the locations of Gulag camps from the Political Repression Victims Database, collected by the historical and human rights association Memorial.[18] Similarly, we also use data on the destination locations of Soviet enterprises evacuated to the east of the USSR during WWII, collected by Markevich and Mikhailova (2013).

Geographical variables.—We also assembled a broad set of geographic characteristics for the destinations of ethnic deportations. We use these variables for the balancing tests and some as controls in regressions. The information about inland water areas and railroads comes from DIVA-GIS.[19] The data on temperature and precipitation come from the Geography Department at the University of Delaware.[20] The information on soil suitability for high and low inputs and the measure of ruggedness come from the FAO GAEZ dataset.[21] We also collected data on the location of historical and present-day capital cities. Using digital maps, we calculate distances to water areas, to railways, to past and present capitals, to Gulag camps, and to the destination locations of enterprises evacuated during the war.

Table Table A3 in the online appendix presents summary statistics of all variables used in the analysis.

3.2 Spatial variation in the composition of ethnic deportees at the destination locations

Panel B of Figure 2 maps the spatial variation that we exploit. It shows the share of Protestants among all Protestant and Sunni Muslim deportees (over 87% of all ethnic deportees) by municipality (district, *rayon*). For presentation purposes, the figure zooms into the geographic area which was the destination of the largest number of ethnic deportees. Thick lines on the figure represent regional boundaries. The map shows that the largest differences in the composition of ethnic deportees were

[21]http://www.gaez.iiasa.ac.at, accessed on April 24, 2019.

across regions. This is consistent with the historical narrative as the central authorities determined the destination region for each deportee group. However, it is also evident from the figure that there is a lot of within-region differences in the composition of ethnic deportees across municipalities. Our analysis uses this variation.[22]

We match the destinations of ethnic deportations to the location of residence of respondents in the Life in Transition survey. In order to do this, we calculate the number of deportees of each ethnic group deported to localities within a 30-kilometer travel distance from each LiTS Primary Sampling Unit (PSU). Out of 375 LiTS PSUs in the five considered countries, Russia, Kazakhstan, Uzbekistan, Kyrgyzstan, and Tajikistan, 233 PSUs had an ethnic deportation within a 30-kilometer travel distance. We use a 30km travel distance to match LiTS PSUs to deportation locations for the following reasons. For many deportations, we could determine their destination at the level of municipality, rather than the exact settlement. The NKVD deportee census provides information on the distances between village settlements of deportees and the local NKVD offices, which kept their record (*spetskommendatura*), and between the local NKVD office and the center of the municipality. The median of both of these distances is about 30 kilometers. As we report below, our results are robust to using alternative buffer thresholds with radii between 20 and 40 kilometers.

Figure A6 in the online appendix presents the religious composition of deportees in each of these 233 PSUs with an ethnic deportation in vicinity. 56 of these PSUs are in Kazakhstan, 62 – in Kyrgyzstan, 59 – in Uzbekistan, 31 – in Tajikistan, and 25 are in Russia. In Figure A7, we summarize the variation in the data at the LiTS respondent level. The figure presents the densities of the number and of the share of Protestant deportees across observations in our sample.

In Figure A8, we present the distribution of the ratio of the number of deportees to the 1939 district population across LiTS PSUs. The mean of this ratio is 0.25 and the median is 0.13. As mentioned above, it is impossible to assess to what extent these figures reflect the share of deportees in the total post-war population of deportation destinations, both because of the population losses during the war and the technical difficulties in mapping 1939 data.

4 Empirical strategy, identification assumptions, and balancing tests

In our empirical strategy, we link the gender norms of respondents in PSUs that were historically exposed to ethnic deportations to the religious composition of these de-

---

[22]Figure A3 in the online appendix presents the composition by traditional religion at destination locations for all ethnic deportees, i.e., including non-Protestant and non-Sunni Muslim deportees.

portations, controlling for region fixed effects, the size of the pre-war local population, and a variety of historical and geographical characteristics. We consider the traditional religion of deportee groups, Protestant vs. Muslim, as a proxy for their pre-deportation gender norms. The main identification assumption is that, conditional on region fixed effects and the presence of deportation near a PSU, the identity of deportees (e.g., their religion, ethnicity, and, as a consequence, cultural characteristics) was orthogonal to any unobserved determinants of the gender norms of the local population.

This identification assumption is untestable, as it concerns unobservables. However, both the historical narrative and the balancing tests which we present below provide strong support for this assumption. In addition, after presenting the main result in Section 5 below, we address identification challenges in two ways: (1) by using techniques developed by Altonji, Elder and Taber (2005) and Oster (2017) to show that it is very unlikely that variation in unobservables could drive our results; and (2) by showing that there are no pre-trends using the education of the mothers of respondents as the outcome of interest.

4.1   Historical rational behind the identification assumption

The between-region allocation of deportees to destinations was designed by the central authorities and could have been guided by ideas of the authorities about the potential effects of mixing different ethnicities at deportation destinations. However, as historians argue, the within-region allocation of ethnic deportees across districts was determined by the need for manual labor at the time of the arrival of each group of ethnic deportees to the main railway station of each destination region. Local administrations were looking for healthy and strong men and women as physical labor was the main occupation of ethnic deportees at destinations. Importantly, the local native population was rather homogeneous within destination regions before the deportations (confirmed by the balancing tests, presented below), making it implausible that representatives of different districts within regions had different preferences about which groups of deportees to accept into their localities.

4.2   Balancing tests

In Table 1, we present the results of three sets of regressions aimed to establish correlates of the main treatment variable. In the first column, we address the question of what observable characteristics correlate with the presence of an ethnic deportation in the vicinity of a particular LiTS PSU. The second and the third columns present the correlates of the share of Protestants among deportees across districts that were the destinations of ethnic deportations. In the second column, the sample is comprised of

18

all such districts, and in the third column, the sample is restricted to districts that include LiTS PSUs with ethnic deportation in the vicinity and, therefore, are in our baseline sample. The unit of analysis is a Soviet district, to which we match all the geographical and historical variables.

In Panel A, we consider a wide range of geography and climate characteristics, such as distances to closest water, railroad, Gulag camp, and capital city, as well as local ruggedness, soil suitability, precipitation, and temperature. To check for a possible confounding policy, we also look at whether the district was also a destination location of evacuated industrial enterprises in 1941. In Panel B, we focus on population characteristics from the 1939 Soviet census: the district's total population and its ethnic composition. In Panel C, we examine the balance in terms of population characteristics from the 1897 Russian empire census: population density, literacy rate, urbanization, and the shares of employed in agriculture, industry, and services, as well as the share of employed in white collar jobs. For Central Asia, we also have data on 1897 local religious composition and literacy for women. In all regressions, we rely on the variation within subnational administrative units. In Panels A and B, we control for fixed effects at the level of Soviet subnational region; in Panel C, we control for fixed effects at the level of 1897 Russian empire provinces, the analogue of the region in the Russian empire.[23]

In Column 1, we regress these characteristics one by one on the dummy indicating that the LiTS PSU was a destination of ethnic deportation. The results clearly indicate that the location of deportation destinations was not random: the majority of the geographical variables and many historical variables are strongly correlated with the presence of deportations even within regions. This is consistent with the historical narrative that deportees were assigned to localities with a higher demand for manual labor.[24]

Columns 2 and 3 present specifications in which we regress these variables on the local share of Protestants among deportees controlling for the total number of ethnic deportees and shares of the deportees with traditional religion other than Protestantism (the treatment) or Islam (the comparison group). In sharp contrast to the results from Column 1, there are few significant correlates of the share of Protestants among ethnic deportees across locations that were the destinations of ethnic deportations. In addition, in all cases where there is a significant correlation, it is not robust to the choice

---

[23]As the data from the 1897 Russian empire census are at the level of Russian empire counties (*uezd*), which are, on average, larger than Soviet districts, in Panel C, we cluster at *uezd*-level. In Panels A and B, the standard errors are corrected for spatial correlation within a 150km radius around the district centeroid, similarly to our baseline specification, described below.

[24]Figure A9 in the online appendix illustrates one of determinants of the deportation destinations, proximity to railroads.

of the sample: either all districts that were the destinations of ethnic deportations (Column 2) or only those districts that are in the vicinity LiTS PSUs (Column 3).[25]

Overall, we conclude that, conditional of subnational-region fixed effects, a battery of geographical, historical, and pre-deportation population characteristics are largely balanced across deportation destinations with different group composition of deportees, just as the historical narrative suggests.

4.3 The main econometric specifications

We aim at estimating the effect of exposure of the local population to deportee groups with different gender norms, using the responses of LiTS participants about their gender attitudes and behavior as outcomes. Even though the vast majority of the deportees left when they were allowed to do so, some stayed. If there are any descendants of deportees still in the destination localities, we ensure that they are not in our sample by restricting the sample to respondents from the majority ethnic group in each country, i.e., Russians in Russia, Kazakhs in Kazakhstan, Uzbeks in Uzbekistan, Kyrgyz in Kyrgyzstan, and Tajik in Tajikistan.[26] We also present robustness of the results to restricting the sample to respondents whose ancestors in 1939 lived in the same region as them.

We estimate two alternative specifications: the first one focuses on the effect of the numbers of deportees from different groups in the vicinity of the respondent's residence, and the second one—on the effect of the shares of deportees from different groups.

The first specification estimates the following cross-sectional equation on the sample of all localities (LiTS PSUs) in Russia and Central Asia:

$$Y_i = \beta_0 + \beta_1 \log(Protestants_{l_i}) + \beta_2 \log(Muslims_{l_i}) + \beta_3 \mathbb{1}\{Deportation_{l_i}\} + \\ + \beta_4 \log(Population\_1939_{l_i}) + \sigma' \mathbf{D_{l_i}} + \gamma' \mathbf{X_{l_i}} + \delta' \mathbf{C_i} + \mu_{r_{l_i}} + \epsilon_i, \quad (1)$$

where i indexes survey respondents and l_i indexes the locality (LiTS PSU) of respondent i. The main explanatory variables are the log numbers of Protestant and Sunni Muslim deportees in the 30-kilometer travel-distance radius around the locality l, $\log(Protestants_{l_i})$ and $\log(Muslims_{l_i})$, respectively.[27] The main control vari-

---

[25]Below, we show that our main results do not change if we include in the list of covariates the variables for which we found statistically significant correlations in Columns 2 and 3, or if we exclude them from our main specification.

[26]It is worth noting that there were very few intermarriages between ethnic deportees and the local population in Central Asia due to racial animosity. Similarly, due to religious animosity, there were very few intermarriages between Chechens and Russians in Siberia. In contrast, there were some intermarriages between Russians and Soviet Germans (Mukhina, 2005). However, all relatives of German deportees were given German passports after the fall of the USSR and, therefore, the vast majority of these mixed families left to Germany together with other German deportees in the early 1990s.

[27]Throughout the paper, we refer to Sunni Muslims as Muslims because the number of Shia Muslim

20

ables, necessary for identification, are the subnational region fixed effects ($\mu_{r_{l_i}}$, where r denotes the region to which locality l belonged) and a dummy variable indicating whether there were any Protestant or Muslim deportees in the vicinity of the locality l, $\mathbb{1}\{Deportation_{l_i}\}$. Region fixed effects ensure that we rely on within-region variation. The dummy for the presence of a Protestant or Muslim deportation in the vicinity of the locality accounts for the selection of localities into the deportation destinations.

Y stands for the following outcome variables: dummy variables indicating whether the respondent either "strongly disagrees" or "disagrees" with each of the following statements: *(1) "A woman should do most of the household chores even if the husband is unemployed"; (2) "It is better for everyone if the man earns the money and the woman takes care of home"; (3) "Men make better political leaders than women do"*; the first principal component of these three outcomes; a dummy variable indicating whether the respondent tried, successfully or not, to start a business; a dummy variable indicating whether the respondent is a member of a women rights association; and a dummy variable indicating whether the mother of the respondent completed tertiary education.

Alternatively, in specification 1, instead of $\log(Protestants_{l_i})$ and $\log(Muslims_{l_i})$, we include separately the logs of the numbers of Germans, Chechens, Crimean Tatars, and Meskhetian Turks, the four largest deportee groups. Chechens were rehabilitated in 1956-1957, unlike these other three groups of deportees who were never "pardoned" and had to stay in their deportation locations until the dissolution of the USSR. However, the difference in the length of exposure between different subgroups of Muslim deportees, was not the only difference. Chechen deportees also had more extreme gender norms compared to other Muslim deportees.

To compare locations where the size of the local native population was similar, we control for the log population in 1939 in the district of the locality l, $Population\_1939_{l_i}$. To have a clean comparison between Protestant and (Sunni) Muslim deportees, we control for the log numbers of ethnic deportees in the 30-kilometer travel distance radius around the respondent's locality separately for each of the other religions: Orthodox Christians, Buddhists, Shia Muslims, and Catholics and Jews together, who we cannot disentangle because both Polish Catholics and Polish Jews were deported together. We also control for the log number of nonethnic deportees. (These controls are denoted by **D**.)

In addition, we control for potential locality-level confounds, such as dummies for urban locations and for capital cities, distances to the closest railroad, capital city,

---

deportees was negligible: only 0.2% of all ethnic deportees were Shia Muslims, as can be seen from Table A1 in the online appendix. Whether we control for them or include them in the group of Muslim deportees makes no difference for any of the results.

Gulag camp, and to the closest water area, ruggedness, summer and winter average temperatures and precipitation, and soil suitability with low- and high-input agriculture ($\mathbf{X}$). We also control for respondent-level determinants of gender attitudes: age, education, log of income, religious denomination, and gender ($\mathbf{C}$). As some of the individual controls can be endogenous, we present results with and without these controls. We also present robustness of the results to controlling for a larger set of pre-deportation population characteristics. As shown below, our main results are unaffected by the inclusion or exclusion of any of the $\mathbf{X}$ and $\mathbf{C}$ covariates.

The second specification uses the share of Protestants among all deportees in the vicinity of locality l, $Protestant\_Share_{l_i}$, as the main explanatory variable:

$$Y_i = \alpha_0 + \alpha_1 Protestant\_Share_{l_i} + \alpha_2 \log(Deportation\_Size_{l_i}) +$$
$$+ \alpha_3 \log(Population\_1939_{l_i}) + \sigma' \mathbf{M_{l_i}} + \gamma' \mathbf{X_{l_i}} + \delta' \mathbf{C_i} + \mu_{r_{l_i}} + \epsilon_i. \tag{2}$$

Equation 2 is estimated on the sample of all localities (LiTS PSUs) with an ethnic deportation settlement in the vicinity.[28] In this specification, we control for the log of the total number of deportees in the same buffer around the respondent ($Deportation\_Size$) and for the shares of all other religious groups of deportees, other than Sunni Muslims, in the vicinity of the respondent's locality ($\mathbf{M}$). The inclusion of these controls ensures that the comparison group is the share of (Sunni) Muslims deportees. As in equation 1, we control for the pre-deportation population size and verify robustness to controlling for historical and geographical characteristics of the locality ($\mathbf{X}$) and socio-economic characteristics of the respondent ($\mathbf{C}$).

To account for spatial correlation in the error term, in both specifications 1 and 2, we correct standard errors for spatial correlation within a 150km radius around the locality (Conley, 1999) and present robustness to alternative assumptions about variance-covariance matrix.

5 The main results

5.1 Baseline

Table 2 presents the main result for gender attitudes as an outcome. In this table, we use the baseline set of controls and establish robustness of the results in the next subsection. Panels A and B focus on the estimation of equations 1 and 2, respectively. Even columns show the results for female respondents and odd columns – for male respondents. The specification with the log numbers of deportees as the main explanatory variable (Panel A) yields significant positive coefficients on the log number of Protestant deportees in the vicinity of the respondent's locality for all outcomes and

---

[28]All PSUs with an ethnic deportation had at least some Muslim or Protestant deportees.

both genders. The coefficients on the log number of Muslim deportees are consistently negative (with the exception of one specification out of eight), but never statistically significant. In all regressions but one, the test for the equality of coefficients yields that the exposure to Protestant and Muslim deportees had a different effect on the gender attitudes of the local population.

Furthermore, despite the fact that the coefficients on the log number of Muslim deportees are less precisely estimated, in most cases, we can reject the hypothesis that the magnitude of the effects of exposure to Protestant and Muslim deportees is similar in absolute value. This suggests that the effect of the exposure to Protestant deportees on gender attitudes is higher than the effect of the exposure to Muslim deportees. P-values for both of these tests are presented at the bottom of Panel A. The results for the effect of the share of Protestants among deportees (presented in Panel B) are consistent with those for the levels: the coefficients on the share of Protestants among Protestant and Muslim deportees are positive for all outcomes and statistically significant in all, but one specification.[29]

Table 3 presents the same specifications for the two respondent-level behavioral outcomes: (attempted) entrepreneurship and membership in women's rights associations. The most striking result is for entrepreneurship among women (Column 1). In localities with a higher number of Protestants among ethnic deportees, women today are significantly more likely to have tried to start a business; whereas in localities with a higher number of Muslim deportees, the effect is reversed: women today are significantly less likely to have tried to start a business. In sharp contrast to the results for female respondents, we find no effect of the composition of ethnic deportations on entrepreneurship rates among male respondents (Column 2). This can be interpreted as a placebo test: it suggests that the differences in the behavior of women that we document in Column 1 are not driven by unobserved characteristics of the localities they live in. If the within-region composition of ethnic deportees had been correlated with unobserved factors that are correlated with entrepreneurship, we would have found similar effects for men and women. The absence of an association between the composition of ethnic deportees in a locality and male entrepreneurship rates is consistent with our identification assumption that the differences in the composition of ethnic deportees affect our outcomes through the differences in exposure to groups with different gender norms rather than differences in the environment.

We also find that an increase in the number of Protestant deportees is associated with significantly higher rates of membership in women's rights associations among men and women (as shown in Columns 3 and 4 of Panel A). As with the attitudes, the effects

---

[29]As the results for the three different questions about gender attitudes are very similar, in what follows, we focus on the first principal component as the main attitudinal outcome.

of the exposure to Muslim deportees on this outcome are imprecisely estimated, but the difference in magnitude of the coefficients on Protestant and Muslim deportees is statistically significant in the sample of male respondents. In Panel B, we show that the share of Protestants among deportees has a positive coefficient for all outcomes—with the exception of the placebo estimation for male entrepreneurship—and is statistically significant for female entrepreneurship (Column 1) and membership in women's right advocacy associations among men (Column 4).[30]

The magnitude of the effects is substantial. If we compare two localities within the same subnational region, such that one was historically exposed to an average-sized ethnic deportation comprised only of Protestants (i.e., mostly, Germans) and the other – only of Sunni Muslims (mostly, Chechens), the residents of the first locality today are 17 percentage points more likely to hold progressive, i.e., more egalitarian, gender attitudes than the residents of the second locality.[31] In addition, in the first locality, women are 13 percentage points more likely to have tried themselves at entrepreneurship. The standard deviation of the share of Protestants among ethnic deportees in locations of ethnic deportations is 35%, which means that a one standard deviation difference in the composition of ethnic deportees is associated with a 6 percentage point difference in gender attitudes. These magnitudes are large relative to the average shares of the population holding progressive gender attitudes (19.5% among women and 16.3% among men). In addition, a one standard deviation difference in the composition of ethnic deportees is associated with a 4.6 percentage point difference in the entrepreneurship rate among women (compared to the 11.6% mean value for this outcome.)

The magnitude of the intensive margin is implied by the specification in levels: a 10% increase in the number of Protestant deportees in the vicinity of a locality leads to a 2.7 percentage point increase in the share of women with progressive gender attitudes and a 1.8 percentage point increase in the share of men with progressive gender attitudes today. It also leads to a 0.9 percentage point increase in the rate of (attempted) entrepreneurship among women. A 10% increase in the number of Muslim deportees leads to a decrease in female entrepreneurship rates by 1.2 percentage points.

5.2 Controls and variation in observables and unobservables

In Tables 4 and 5, we establish robustness of the main results to changes in the set of covariates.

---

[30]If what follows, we focus on the female entrepreneurship as the main outcome measuring respondent's behavior because the rates of membership in women's right advocacy associations are, on average, very low; and therefore, the variation in this outcome is limited.

[31]This can be seen from the magnitude of the coefficients on the share of Protestant deportees in regressions for the first principal component of all gender attitudes that is normalized between 0 and 1, i.e., the last two columns of Panel B of Table 2.

Table 4 presents the results of the estimation of equation 1. In Panel A, we consider the first principal component of gender attitudes as the dependent variable. We pool respondents of both genders together because the results for male and female respondents for this outcome are similar (as reported in Table 2). In Panel B, the dependent variable is the entrepreneurship dummy and we focus on the sample of female respondents.

In Column 1, we restate the main result using the baseline set of controls considered in Section 5.1 above. In Column 2, there are no controls with the exception of region fixed effects, which are necessary to the main identification assumption. In Column 3, we additionally control for possible selection of localities into deportation destinations, which is important for identification. In Column 4, we add controls for the size of non-Protestant and non-Muslim deportations in the vicinity of the locality. In Columns 5 and 6, we also add locality-level (geographical and historical) controls and respondent's age, gender, and religion. The baseline specification (Column 1) adds to this list of covariates two potentially endogenous but important determinants of gender norms: respondent's income and education. In Column 7, we add all historical covariates that show any sign of misbalance in the balancing Table 1. Finally, in Column 8, we add another two potentially endogenous variables, educational attainment of respondent's parents, into the set of covariates. We find that the results do not depend on the set of controls: both the point estimates and the significance levels are stable across specifications.

In Panels A and B of Table 5, we repeat this exercise for the effect of the share of Protestant deportees, i.e., the estimation of equation 2. Panel A presents the results for the gender attitudes and Panel B – for female entrepreneurship.[32] Again, we find that the results are robust and do not depend on the set of covariates.

Following the methodology developed by Altonji, Elder and Taber (2005) and Oster (2017), we can test whether our results are likely to be driven by variation in unobserved confounders under the assumption that observables represent unobservables. We focus on the effect of the share of Protestants among deportees because, in this specification, there is only one explanatory variable of interest. First, for each set of covariates considered in different columns of Table 5, we construct an index of covariates that is the best predictor of our treatment variable by taking the fitted value from a regression of the share of Protestants among deportees on these covariates. Then, we regress the outcome variables on these indices controlling for region fixed effects. The results are presented in the first two rows of Panels C and D of Table 5. The predicted-from-

---

[32] As the specification in shares relies of the subsample of localities with ethnic deportations, Table 5 has 7 columns and not 8 as in Table 4. This is because the dummy for being a destination of ethnic deportations—which is added to the set of covariates in Column 3 of Table 4—is always equal one in Table 5.

observables share of Protestant deportees is not significantly related to our outcomes of interest. Furthermore, in the last row of Panels C and D of Table 5, we present the Oster's δ statistics with region fixed effects kept as necessary controls.[33] Once we include controls for the exposure to other deportation groups and the basic locality characteristics, the magnitude of Oster's statistics makes it very unlikely that the results can be explained by variation in unobservables.

5.3 Testing for pre-trends

The educational attainment of respondents' mothers is the only outcome variable which we can measure both pre- and post-treatment. We predict the birth year of the mother of each respondent using respondent's age and the aggregate data on the average age of women giving birth by women's birth cohort in the USSR. Then, we compare the rate of attainment of tertiary education by mothers of respondents, depending on the composition of deportees in the respondent's locality and the timing of the mothers' compulsory schooling.

First, we group all respondents into two birth-cohort groups. The first group consists of respondents with mothers old enough to have finished compulsory schooling before WWII and, therefore, before the arrival of the deportees. The second group consists of respondents with mothers who went to school when the deportees arrived or afterwards. Column 1 of Table 6 presents the results of estimation of the effect of living in localities with Protestant or Muslim deportees on mothers' education separately for these cohort groups. This is operationalized by adding interactions of the main treatment variables with the birth-cohort-group dummies. Panels A and B correspond to the specifications in levels and in shares, respectively. Given that the outcome is specific to the mother of the respondent, we omit the respondent's socio-economic controls, making the list of covariates similar to Column 6 of Table 1 and Column 5 of Table 2. In addition to these controls, we include dummies for each birth-cohort group into the list of covariates.

We find no effect of the group composition of deportees in the vicinity of a locality on the educational attainment of mothers who completed their compulsory schooling before the arrival of deportees. In contrast, the group composition of deportees matters for the educational attainment of mothers who did their compulsory schooling with the children of deportees. In particular, exposure to Protestant deportees during the time of compulsory primary and secondary education had a significant positive effect on the probability of the mothers of respondents to complete tertiary education. There is

---

[33]Following Oster (2017), we set the value of $R^2_{\max}$, the R^2 from a hypothetical regression of the outcome on treatment and both observed and unobserved controls, to be equal to $1.3\tilde{R}^2$, where $\tilde{R}^2$ is the R^2 from the corresponding regression from Panels A and B of Table 5.

also a negative, but imprecisely estimated effect of exposure to Muslim deportees. A 10% increase in the number of Protestant deportees in the vicinity of the locality led to a 0.6 percentage-point increase in the tertiary-education attainment of respondents' mothers who attended school during or after the deportations. Under the assumption that it is harder to enroll in school again after dropping out than to continue education without a break, these results suggest that being educated alongside the children of Protestant deportees increased the probability that local native girls continued their education beyond compulsory schooling. The fact that there is no result for cohorts of mothers who finished their compulsory schooling before the war strongly suggests that there are no pre-trends.

Second, we split the second group of respondents into two groups: with mothers who had partial exposure and mothers who had full exposure, i.e., mothers who were of the age of compulsory schooling during WWII (the time when education was likely to be disrupted) and mothers who started compulsory schooling after the end of the war and, therefore, did all of their schooling after the deportees had arrived.[34] Column 2 presents the results: it shows that the effects are significant only for the full exposure cohort.

Panel A of Figure 4 provides an illustration of these results. It presents the estimated coefficients in regressions of mother's education on the share of Protestant deportees (along with 90% confidence intervals) by cohort group of respondents. The first two groups on these graphs correspond to the first two groups from Column 2 of Table 6, i.e., mothers educated before WWII and mothers educated during WWII. The other three groups represent an equal-sample split of the group of respondents with mothers educated after WWII. The figure shows that the effect is positive and statistically significant starting with the oldest cohort that went to school right after the war.

Panel B of the Figure 4 presents a similar graph, but for gender attitudes of respondents in the same cohort groups. It shows that the effect of exposure to deportees on the gender attitudes of respondents is not fully mediated by its effect on the level of mother's education. In particular, there is a strong and significant effect of the share of Protestant deportees on gender attitudes of respondents both for those cohorts whose mothers have completed compulsory schooling before deportees arrived and for those cohorts whose mothers went to school after deportees arrived.[35]

---

[34]The mothers of respondents from the youngest group went to school together with children of German, Crimean Tatar, and Meskhetian Turk deportees—as these groups were never pardoned; and depending on their age, either together with children of Chechen deportees or after Chechens had left during Khrushchev's Thaw.

[35]Figure A10 in the online appendix illustrates the corresponding results from estimation of equation 1 presented in Panel A of Table 6.

Electronic copy available at: https://ssrn.com/abstract=3417682

5.4 Ethnic rather than religious groups of deportees

In Table 7, we focus on the ethnic rather than the religious groups of deportees. In particular, we consider the effect of exposure to the four largest groups of deportees: Germans, Chechens, Crimean Tatars, and Meskhetian Turks separately.[36] For this analysis, in order to have a clear comparison group, in addition to our baseline controls, we also control for the log numbers of *other* Muslims and *other* Protestants among deportees (who were very few).

First, the results confirm that the effect of exposure to German deportees is the same as the effect of exposure to all Protestant deportees, which is expected as these groups were essentially the same. Second, we find a strong, negative, and significant effect of exposure to Chechen deportees not only on female entrepreneurship, as is the case for the exposure to all Muslim deportees, but also for gender attitudes. In absolute value, the point estimates of the coefficients estimating the effect of exposure to Chechens on gender attitudes is about one half of those for the effect of exposure to Germans, but we cannot reject the equality of the absolute magnitudes of these opposite-sign effects.

In contrast to the strong effects of exposure to Chechens, there is no effect of exposure to Crimean Tatars or Meskhetian Turks on gender attitudes: the point estimates do not have a consistent sign and the standard errors are large. At the same time, the sign of the effects of exposure to each subgroup of Muslim deportees on female entrepreneurship is consistently negative, and this effect is significant for exposure to the two largest groups of Muslim deportees: Chechens and Crimean Tatars.

The fact that we find strongest results for Chechens, suggests that the 15 years of exposure to Chechens was enough to change the attitudes of the local population. Chechen deportees were more numerous than other Muslim deportees and, as we discussed in the background section, their gender norms were the most extreme.

5.5 Discussion of the differential effect of exposure to Muslim vs. Protestant deportees

Overall, we find robust evidence of a positive effect of exposure to Protestant deportees on gender norms manifesting itself both in attitudinal measures and behavior (i.e., female entrepreneurship, tertiary education of respondents' mothers, and membership in women rights associations). A negative effect of the exposure to Muslim deportees on female entrepreneurship is also strong and robust. However, the effect of exposure to Muslim deportees on gender attitudes is less robust and driven solely by the exposure

---

[36]Ethnic Germans constituted 96.5% of all Protestant deportees; and Chechens, Crimean Tatars, and Meskhetian Turks together constituted 95% of all Sunni Muslim deportees.

to one sub-group of Muslim deportees, namely, Chechens. Furthermore, the negative effect of exposure to Chechen deportees on gender attitudes is (substantially, but not significantly) smaller in absolute value than the positive effect of exposure to German deportees. What could potentially explain this asymmetry?

The theoretical literature on cultural transmission highlights the costs and benefits of adopting cultural traits (see, for instance, a survey by Bisin and Verdier, 2010). In post-war USSR, the costs of adopting more gender equal norms were smaller and the benefits of adopting these norms higher than those of adopting less gender equal norms. First and foremost, norms of gender equality were in line with the official ideology, which implies that adopting non-gender-equal norms may have been costly due to possible retribution by the state. Second, there were tangible economic benefits from adopting norms of gender equality: educated women earned higher wages and had more stable jobs in the Soviet Union. Both of these considerations imply that progressive gender norms should diffuse more. Finally, it could also be the case that Soviet Germans provided a better role model, as they may have been perceived to be more educated, with higher work ethnic, and more cooperative than Chechens by the local population at destination locations (Pohl, 2008, p. 212); if so, this could have made their culture more appealing to the local population.

We cannot distinguish between these different explanations for why the effects of exposure to Muslim deportees on the self-expression of gender-related attitudes are generally weaker than the effects of exposure to Protestant deportees. It is worth reiterating, however, that the effects on female entrepreneurship are equally strong.

We do not have data to pin down the exact mechanism at play. It is clear, however, that one can exclude inter-group marriages as the main mechanism behind the horizontal transmission of gender norms because there were too few inter-group marriages. Thus, informal interactions between the representatives of different groups must have led to horizontal cultural transmission. Our results about mothers' educational attainment, for example, point to the importance of contact at school as one of the places where the norms were diffused.

5.6 Additional robustness checks

In the baseline estimation, we use the Conley correction of standard errors for spatial correlation at a radius of 150km. In Table A5, we report robustness to alternative assumptions about the variance-covariance matrix. The results are robust to clustering at the LiTS-PSU level, at the subnational region level, and to increasing the Conley radius to 200 kilometres. Table A6 reproduces the main results using LiTS-PSU-level aggregated data.

Our baseline measure of the exposure of local population to deportees uses the

numbers of Protestant and Muslim deportees in the 30-kilometer travel distance vicinity of LiTS PSUs. Figures A11 and A12 in the online appendix visualize the results of a robustness exercise in which we change the radius in the definition of the vicinity of a locality used for calculating the numbers of deportees around the LiTS PSUs. We plot the estimated coefficients along with their confidence intervals on the explanatory variables of interest for the main outcomes with radii equal to travel distances of 10, 20, 30, 40 and 50 kilometers. We find that the results are the strongest with the 30-kilometer radius, but they are largely robust to using radii between 20 and 40 kilometers.

6 Heterogeneity by cultural distance

To examine whether cultural distance between the deportees and the local native population affects the horizontal transmission of norms, we construct the religious and linguistic distances between the respondents and the deportees following the literature on cultural distances (surveyed in Spolaore and Wacziarg, 2016).

We use the religious tree developed by Mecham, Fearon and Laitin (2006) (reproduced on pp. 190-191 of Spolaore and Wacziarg, 2016) to define religious distance between each pair of a deportee group and a native-population group. In particular, we count the number of branches of the religious tree that one needs to climb in order to reach a common node starting from the nodes of the traditional religions of these groups. There are two traditional religions of the local majorities (and therefore, of the respondents in our sample): Russian Orthodox Christianity and Sunni Islam.[37] In Panel A of Table A4, we present the distances between the religions of native-population groups and traditional religions of the main ethnic deportee groups, Protestant Christianity and Sunni Islam.

We calculate linguistic distances between ethnic groups following the methodology of Bakker et al. (2009), which is based on an adaptation of the "Levenshtein distance" to a pre-defined set of basic notions in each language.[38] The local ethnic majorities encompass four linguistic groups: Russian, Kazakh, Kyrgyz, Tajik, and Uzbek. We also consider the four linguistic groups of the deportees: German, Chechen, Crimean Tatar, and Turkish. Panel B of Table A4 presents the linguistic distances between each pair of these groups. In practice, Protestant deportees were predominantly German; however, many deportation localities included Muslim deportees of different linguistic

---

[37]There are small Shia religious minorities living in Central Asia; none of them are among LiTS respondents.

[38]The data and the code to calculate linguistic distances come from the Automated Similarity Judgment Program database (Wichmann, Holman and Brown, 2018), `https://asjp.clld.org` accessed on September 6, 2019.

groups. To calculate linguistic distance between the respondent and the mixture of Muslim deportees in the respondent's locality, we take an average of linguistic distances between the respondent's language and the languages of each of the Muslim deportee group in the vicinity of locality, weighted by the number of deportees in this group.

In terms of religion, native Russians are closer to Germans than to any of the Muslim deportee groups; and the converse is true for native Central Asians. In terms of language, Kazakhs, Kykgyz, and Uzbeks are relatively close to Crimean Tatars; but all the other pairs of languages are fairly distant.[39]

In Table 8, we test whether cultural distance matters for the horizontal transmission of gender norms. We add interaction terms between the log numbers of Protestant and Muslim deportees and the (demeaned) religious and linguistic distances between respondents and Protestant and Muslim deportees. In the case of linguistic distances, we also control for their direct effect (the religious distances are subsumed by the fixed effect of respondent's traditional religion). The first two columns consider the effect on gender attitudes and the second two – on female entrepreneurship. Columns 1 presents the heterogeneity of the effect of the exposure to deportees by religious distance. The coefficients on the interactions with religious distance have the same sign as the direct effects of the exposure to Protestant and Muslim deportees, suggesting that natives changed their attitudes more as a result of exposure to deportees when they were more culturally different from them (in terms of religion). However, only one out of two coefficients—the one on the interaction term between the log number of Protestant deportees and religious distance—is statistically significant, implying that Central Asians, on average, responded to exposure to Protestant gender norms more than Russians in Siberia. Column 2 shows that there is no significant heterogeneity of the effect of exposure to deportees on gender attitudes with respect to linguistic distance. In contrast to the results for attitudes, we find no heterogeneity with respect to religious distance (as can be seen from Column 3), but the effect of exposure to Muslim deportees on female entrepreneurship is magnified by linguistic distance (Column 4). It is important to note that linguistic distance to Muslim deportees is positively correlated with the share of Chechens among Muslim deportees. As we have discussed, Chechen deportees had the most regressive gender norms. Thus, one cannot differentiate between two alternative explanations of the result presented in Column 4: it could be due both to heterogeneity with respect to linguistic distance and to heterogeneity in the intensity of the treatment itself, i.e., heterogeneity in gender norms, which could be interpreted as a different kind of cultural distance.

---

[39]The linguistic and religious distances are negatively correlated for Central Asian respondents in our sample. This is mostly due to the fact that the language of the most numerous group of Muslim deportees, Chechens, is particularly far from Central Asian languages, yet Chechens and Central Asians share the same religion.

Electronic copy available at: https://ssrn.com/abstract=3417682

Overall, the evidence is not inconsistent with the hypothesis that horizontal inter-group transmission of gender norms is stronger when groups are culturally more distant. Yet, this evidence is rather weak and cannot be considered conclusive: few estimated coefficients on the interaction terms are statistically significant.

7 Evidence against alternative explanations: selective in- and out-migration

In this section, we examine whether selective migration of locals into or out of deportation destinations may drive our results. Theoretically, group composition of deportees could have triggered both selective in and out migration of the local non-deportee population depending on their cultural preferences because—unlike deportees—the non-deportee population was (relatively) free to move.[40] If those locals whose norms diverged the most from the norms of deportees were more likely to migrate into areas without deportations, our results could be driven by selective out-migration rather than cultural diffusion. Similarly, if the presence of deportees at destination locations attracted migrants with certain cultural characteristics, our results could be driven by selective in-migration. To address these alternative explanations, we use the LiTS question about the place of residence of respondents' ancestors before WWII. More precisely, the respondents provided the name of the country and the subnational region of the place of residence of their ancestors in 1939, which we geo-referenced.

First, we test whether selective in-migration could drive our results. We limit the sample to respondents who report that their ancestors in 1939 lived in the same subnational region as the respondent. Table 9 replicates our main results in this sub-sample. Similarly to the baseline results, we find significant effects of exposure to Protestant deportees on both attitudes and female entrepreneurship and of exposure to Muslim deportees on female entrepreneurship. Given that restricting the sample to those whose families did not move since before WWII does not change our results, selective in-migration after WWII into the destination locations of ethnic deportations cannot be a driver of our results.

Second, we test for selective out-migration. We consider the sample of LiTS respondents whose ancestors before WWII lived in regions that during WWII became the destinations of ethnic deportations. The sample includes all those respondents in the 5 countries that we study—countries that were the destinations of ethnic deportations—irrespective of locality where respondents live now. We estimate a linear probability model that explains out-migration from a deportation-destination region depending

---

[40]It is worth noting, however, that post-war mobility of population in the USSR was rather low, as the institution of *Propiska* created administrative restrictions on mobility for all Soviet citizens.

on the composition of ethnic deportations in that region. The unit of observation is an ancestor. We consider all ancestors who lived before the war in the regions that became the destinations of ethnic deportations during the war. There are 8,367 such ancestors. We regress a dummy for whether the respondent in 2016 lived in a different region from the region of his or her ancestor in 1939 (i.e., the ancestor's family out-migrated) on the log numbers of Protestant and Muslim deportees in the ancestor's region of origin. As we only know the place of origin of respondent's ancestors at the level of subnational region, in contrast to all other regressions, we cannot control for region fixed effects in this analysis. We control for the fixed effects of the country of origin of the ancestor and of the country of the destination of the respondent. We also control for the number of LiTS PSUs in each of the region of origin and for whether the ancestor comes from the mother's or father's side of the respondent. Standard errors are corrected for two-way clusters by respondent and by the region of the respondent's ancestor.

The first column of Table 10 presents the results. We find no significant effect of the size of Protestant and Muslim deportations in a region on the probability that people moved out of this region between 1939 and 2016. This suggests that that our baseline results are not driven by selective outmigration. However, one could imagine that the reasons for selective outmigration as well as constraints on mobility for local population were different in Russia and Central Asia. To test whether this was the case, in Column 2 of Table 10, we add the interaction terms between the numbers of Protestant and Muslim deportees and a dummy for whether the respondent's ancestor lived in Russia (rather than in Central Asia). The coefficients on these interactions are also not statistically significant, providing further evidence that selective out-migration cannot drive our results.

Thus, we conclude that our results are driven by horizontal cultural transmission.

8   Conclusions

We study between-group horizontal cultural transmission using Stalin's ethnic deportations as a unique historical experiment in which the coexistence of different ethnic groups was exogenously imposed in a real-world setting. Ethnic groups with drastically different gender norms were deported to locations in Siberia and Central Asia in such a way that the variation in the group composition of deportees within subnational regions was unrelated to the characteristics of localities, to the structure of the local population, or to local gender norms.

Relying on this exogenous variation, we find strong evidence of the diffusion of gender norms from deportees to the local population. Both the norms of gender equality

and of gender discrimination were adopted by people exposed to a deportee group with those norms. The horizontal transmission of norms of gender equality was substantially stronger than that of norms of gender discrimination. This could be explained by higher political costs of adopting norms that go against official state ideology and by economic benefits for households that adopt egalitarian gender norms.

In contrast to other studies of exogenous group exposure, there were no constraints on and no encouragement of interactions between deportees and the local population at the deportation locations. Therefore, our results show that horizontal between-group cultural transmission may occur even without regulating communication between groups or a common goal that unites them.

A broader implication of our analysis is that the formation of cultural ghettos, where different groups live in close proximity but do not learn from each other, is not inevitable.

Figure 1: Mean difference in gender outcomes between locality and its region, by tercile of the share of Protestants in vicinity of locality

(a) Gender attitudes   **(b)** Female entrepreneurship

39
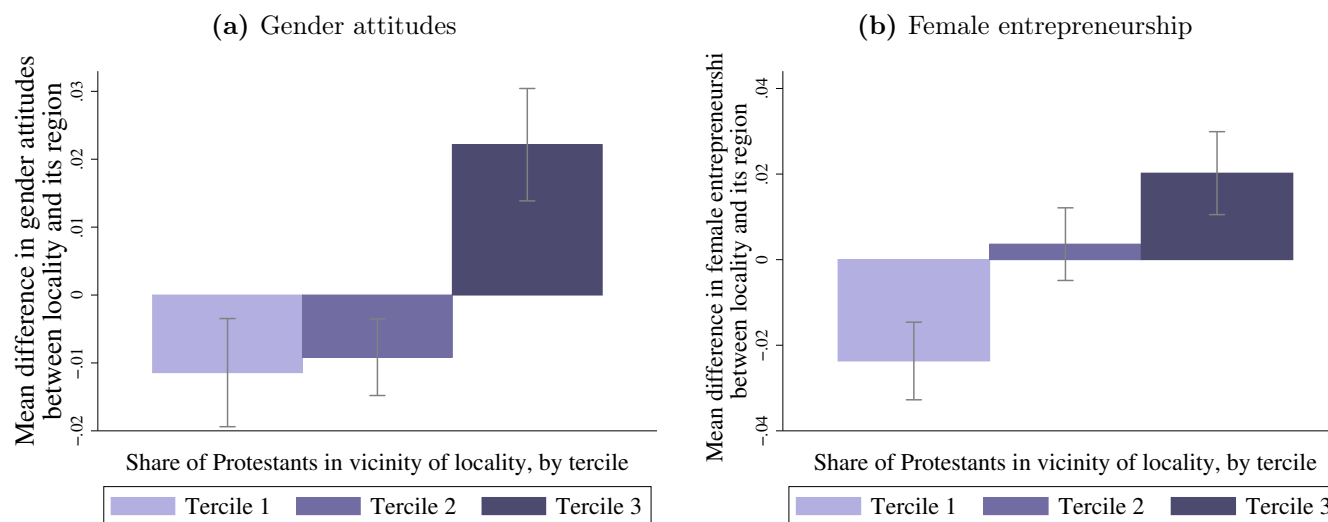

Note: The figure presents the mean difference between an outcome variable for respondents in a locality and respondents in the region of this locality, by the tercile of the share of Protestants among all deportees in the locality. The mean share of Protestants among all deportees is -14 percentage points in the first tercile, 0 - in the second tercile, and + 14 percentage points in the third tercile. In Panel A, the outcome variable is the first principal component of the gender attitudes, calculated from dummies indicating answers "strongly disagree" or "disagree" to each of the following statements: *(1) "A woman should do most of the household chores even if the husband is unemployed"; (2) "It is better for everyone if the man earns the money and the woman takes care of home"; (3) "Men make better political leaders than women do".* In Panel B, the outcome variable is the dummy indicating whether a female respondent tried to start a business.

Figure 2: Density and religious composition of ethnic deportations at destinations

Panel A: Density of ethnic deportees at destination
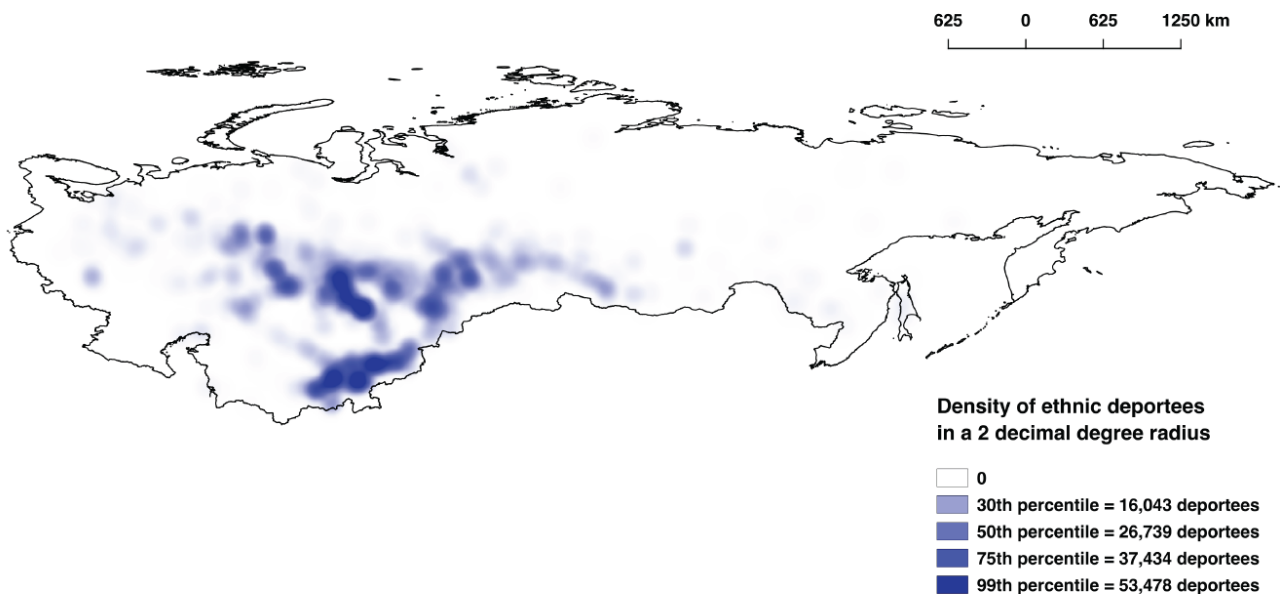

Panel B: The share of Protestants among all Protestant and Muslim deportees at destination
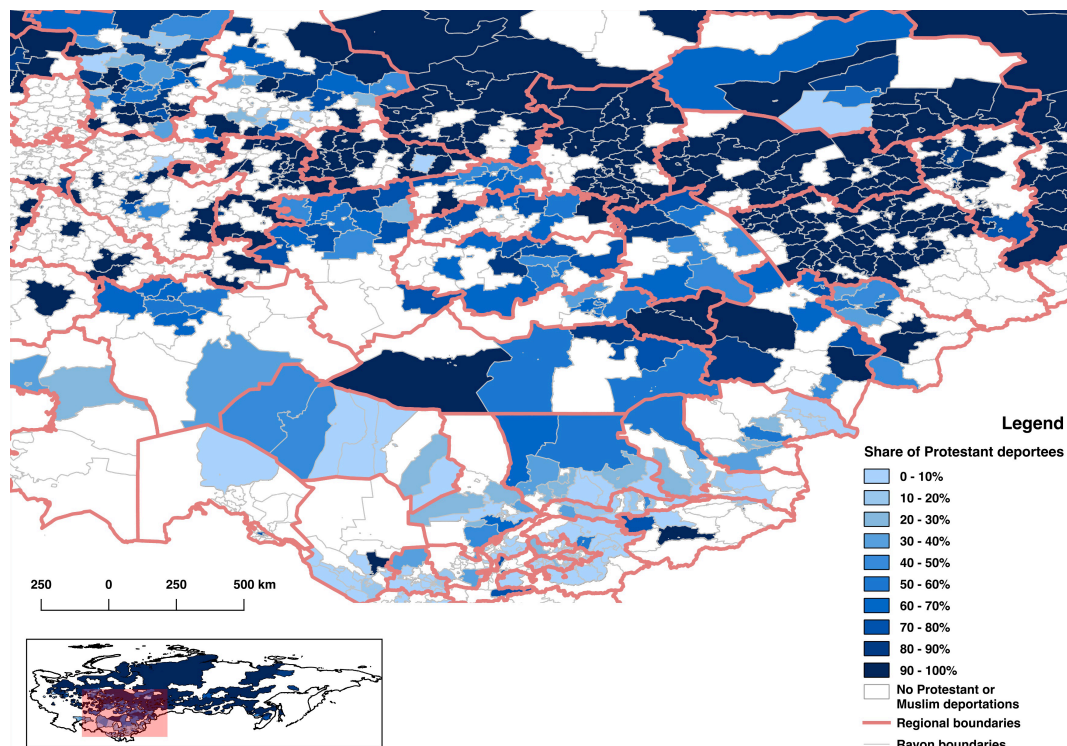

Note: The map in Panel A presents the destination locations of ethnic deportations. The intensity of color indicates density of ethnic deportees in a 2 decimal degree radius, estimated using a quartic (bi-weight) kernel function. The represented values are winsorized at the 99th percentile of the distribution. The legend shows values at 0, 30, 50, 70, and 99th percentiles. The map in Panel B zooms into the area which was the destination of most the sizable ethnic deportations and presents the district-level variation in the share of Protestants among all Protestant and Muslim deportees; this map also presents regional boundaries (in the analysis, we rely on the within-region variation). Figures A2 and A3 in the online appendix present the maps of the exact destinations of deportations and details about their size and group composition.

Figure 3: Gender norms of the two main deportee groups before and after deportations

Pre−existing differences in literacy, 1897
Weighted mean of literacy rate in a province given gender and ethnicity
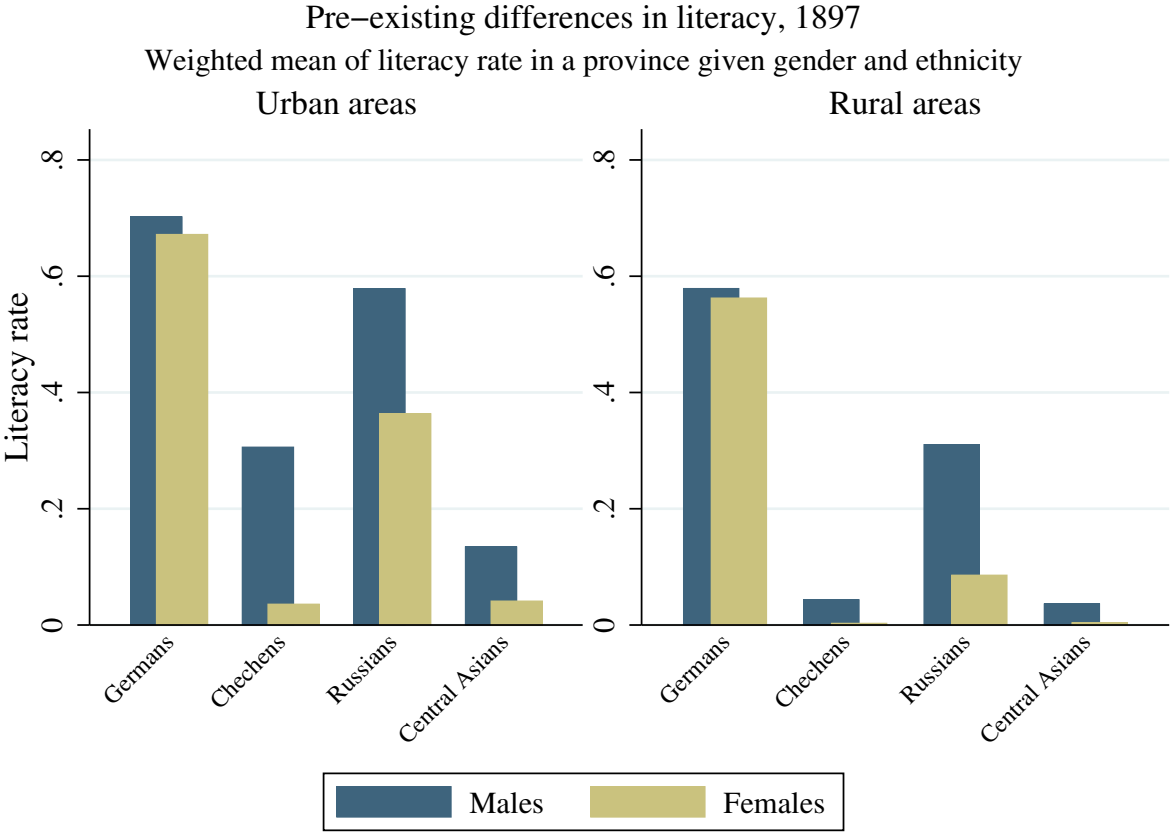

Note: The figure presents the mean weighted literacy rate by gender and ethnicity across provinces in 1897, for urban and rural areas separately. The mean is weighted by the number of people in the ethnic group in the province. The German and Chechen ethnicities make up the largest groups of Protestants and Muslims deportees, respectively. Russians and Central Asians represent the main native populations at the deportation locations.

Figure 4: The time-varying effect of the share of Protestant deportees
on mothers' education and respondents attitudes

(a) Tertiary education of respondents' mothers, by predicted birth cohorts of mothers

(b) Gender attitudes of respondents, by birth cohorts of respondents

Note: Panel A presents the effect of the share of Protestant deportees on the tertiary education of mothers of respondents by mother's predicted birth cohort. Panel B presents the effect of the share of Protestant deportees on the 1st Principal Component of progressive gender attitudes, by birth cohort of respondent. There is a one-to-one correspondence between birth cohorts of respondents and birth cohorts of the mothers. The coefficients and 90% confidence intervals displayed are from the OLS regressions described in the text. Individual and destination location controls as well as cohort-group fixed effects are included. Standard errors are corrected for potential spatial correlation within a radius of 150km following Conley (1999). The two vertical lines on Panels A and B mark three groups of respondents mothers: 1) those with no exposure (i.e., respondents' mothers who finished secondary school before deportations occurred); 2) possible exposure (i.e., mothers who did their secondary school during WWII) and 3) full exposure (i.e., mothers who went to school after the deportations took place). Figure A10 in the online appendix, shows similar graphs for the time-varying effect of the size of Protestant and of Muslim deportations.

Share of literate females	-0.015	(0.011)	228	-0.013	(0.038)	335	-0.010	(0.012)	169

Note: *** $p<0.01$, ** $p<0.05$, * $p<0.1$. Each row-column pair reports results from a separate regression. Each row represents regressions with a different placebo outcome variable. In Column 1, the main explanatory variable is the dummy that equals one if the LiTS PSU was a destination of an ethnic deportation. In Columns 2 and 3, the main explanatory variable is the share of Protestants among deportees. In regressions with the share of Protestant deportees (Columns 2 and 3), we control for the shares of all other ethnic deportee groups (except for Sunni Muslims) and the nonethnic deportees and the log of the total size of deportations. In Panel A and B, we control for region fixed effects. In Panel C, we control for 1897 province and country fixed effects in Column 2 and only for country fixed effects in Column 3, as there is not enough variation after controlling for province fixed effects in this subsample. In addition, we control for the distance to capital city, distance to the railroad, and summer and winter precipitation and temperature in all regressions involving non-geographical outcome variables. Standard errors are corrected for potential spatial correlation within a 150km radius following Conley (1999) in Panels A and B. Standard errors are corrected for clusters at the 1897 uezd level in Panel C.

Region FE and controls	✓	✓	✓	✓	✓	✓	✓	✓

Note: *** p<0.01, ** p<0.05, * p<0.1. Panel A presents our main specification in levels. In Panel A, all regressions control for the size of all other deportee groups. Panel B presents the specification in shares. In Panel B, all regressions control for the share of all other deportee groups (excluding Sunni Muslims) and the total size of deportations. In both panels, the sample is restricted to representatives of the majority group in each country, and in Panel B the sample is further restricted to PSUs within 30km of a deportation. All regressions are conditional on religious group dummies and region fixed effects and on a set of individual controls (age, education and log of income) and geographic controls (log of 1939 population, distance to the closest railroad, capital city, water, and Gulag camp, past/current capital and current urban status, ruggedness, soil suitability for high and low inputs, and average long-run precipitation and temperature in summer and winter). Standard errors are corrected for spatial correlation within a 150km radius following Conley (1999). The dependent variable in columns (7) and (8) is the first principal component of questions used in columns (1) to (6), normalized to a range between 0 and 1.

Note: *** p<0.01, ** p<0.05, * p<0.1. Panel A presents our main specification in levels. In Panel A, all regressions control for the size of all other deportee groups. Panel B presents the specification in shares. In Panel B, all regressions control for the share of all other deportee groups (excluding Sunni Muslims) and the total size of deportations. In both panels, the sample is restricted to representatives of the majority group in each country, and in Panel B the sample is further restricted to PSUs within 30km of a deportation. All regressions are conditional on religious group dummies and region fixed effects and on a set of individual controls (age, education and log of income) and geographic controls (log of 1939 population, distance to the closest railroad, capital city, water, and Gulag camp, past/current capital and current urban status, ruggedness, soil suitability for high and low inputs, and average long-run precipitation and temperature in summer and winter). Standard errors are corrected for spatial correlation within a 150km radius following Conley (1999).

Region and birth-year FE and baseline controls; sample: both genders	✓	✓

Note: Panel A presents our main specification in levels. In Panel A, all regressions control for the size of all other deportee groups. Panel B presents the specification in shares. In Panel B, all regressions control for the share of all other deportee groups (excluding Sunni Muslims) and the total size of deportations. In both panels, the sample is restricted to representatives of the majority group in each country. All regressions are conditional on religious group dummies, region fixed effects, cohort-group fixed effects, and on a set of individual controls (gender of respondent and mother's predicted age) and geographic controls (log of 1939 population, distance to the closest railroad, capital city and Gulag camp, past/current capital and current urban status, ruggedness, and the average long-run summer precipitation and temperature). Standard errors are corrected for spatial correlation within a 150km radius following Conley (1999). The thresholds for mother's birth year that define groups are as follows: in column 1, it is 1925/1926; in column 2, they are 1925/1926 and 1930/1931.

Mean of dependent var.	0.370	0.370
SD of dependent var.	0.483	0.483
Country of destination and country of origin FEs	✓	✓
Number of PSUs in region	✓	✓
Clustered by region of origin and by respondent	✓	✓
Sample: regions of origin with deportations	✓	✓
Sample: ancestor's side	Both	Both

Note: *** $p<0.01$, ** $p<0.05$, * $p<0.1$. The dependent variable is a dummy equal to one if the respondent lives in a different region than the region of residence of his/her ancestors in 1939. The unit of analysis is respondent's ancestor. The sample is comprised of all ancestors from regions with Protestant or Muslim deportation. All regressions control for the size of all other deportee groups, log of 1939 population, the number of LiTS PSUs in the region, and the gender of the parent. The regressions also control for country of destination fixed effect and country of origin fixed effects. Two-way clusters are applied: by respondent and by the region of origin of the ancestor.

A   Online Appendix

Note: *** p<0.01, ** p<0.05, * p<0.1. The table presents the pre-existing differences in gender gap in literacy across the main ethnic groups of deportees and of the local population. Columns 1 to 4 of the Table present regressions by gender × ethnic group × province. The dependent variable in columns 1 to 4 is the literacy rate in a province × ethnicity × gender subgroup of the population. We regress it on a set of dummies indicating whether the subgroup is female, which ethnic group it is, and the interactions between females and considered ethnic groups. In columns 1 and 2, the sample consists of Germans, Chechens and Russians, so that the comparison group is Russian males; and in columns 3 and 4 the sample consists of Germans, Chechens and Central Asians, so that the comparison group is males of Central Asian origin. Columns 5 and 6 present the pre-existing differences in gender gaps in literacy between Muslim and Protestant groups that were subsequently deported. The dependent variable in columns 5 and 6 is the literacy rate in a province × religion × gender subgroup of the population. We regress it on a set of dummies indicating whether the subgroup is female, Protestant, and the interaction between females and Protestants, leaving Muslim males as the comparison subgroup of the population. In all regressions, we control for the average literacy rate of the entire population in each province by gender and correct standard errors for clusters at the province level. Each observation is weighted by the number of people in it, i.e., in the province × ethnicity × gender group in columns 1 to 4 and in the province × religion × gender group in columns 5 and 6.

Table A3: Summary statistics

Sample:	All PSUs				PSUs with deportations			
	Mean	SD	Min	Max	Mean	SD	Min	Max
Main outcomes:								
Disagree: A woman should do most of the household chores	0.17	0.37	0.00	1.00	0.15	0.36	0.00	1.00

Region FE and Controls	✓	✓	✓

Note: *** p<0.01, ** p<0.05, * p<0.1. Panel A presents our main specification in levels, with all variables aggregated to the mean of the Primary Sampling Unit (PSU). All regressions control for the size of all other deportee groups. Panel B presents the specification in shares. All regressions control for the share of all other deportee groups (excluding Sunni Muslims) and the total size of deportations. In both panels, the sample is restricted to the PSU mean of representatives of the majority group in each country for females and males separately, and in Panel B the sample is further restricted to PSUs within 30km of a deportation. All regressions are conditional on the share of Muslim respondents in the PSU, region fixed effects, a set of PSU-level demographic controls (mean age, shares of different levels of education, and mean log of income) and geographic controls (log of 1939 population, distance to the closest railroad, capital city, water, and Gulag camp, past/current capital and current urban status, ruggedness, soil suitability for high and low inputs, and average long-run precipitation and temperature in summer and winter). Standard errors are corrected for spatial correlation within a 150km radius following Conley (1999).

Figure A1: Deportees on the road to destination and at work at destination

**(a)** Chechen deportees on the road to destination

**(b)** Volga German deportees at work in Siberia

Note: Copyright for Panel (a): Wikimedia Commons; for Panel (b): Alamy (www.alamy.com).

**Figure A2:** Destination locations of all ethnic and nonethnic deportations

Note: The map presents deportation locations of all ethnic and nonethnic deportees, as recorded in 1951 deportation census. Nonethnic deportations were comprised mostly of "Kulaks" (wealthy farmers expropriated during the collectivization), but also of "other anti-Soviet elements."

60

Figure A3: Religious composition and size of ethnic deportations
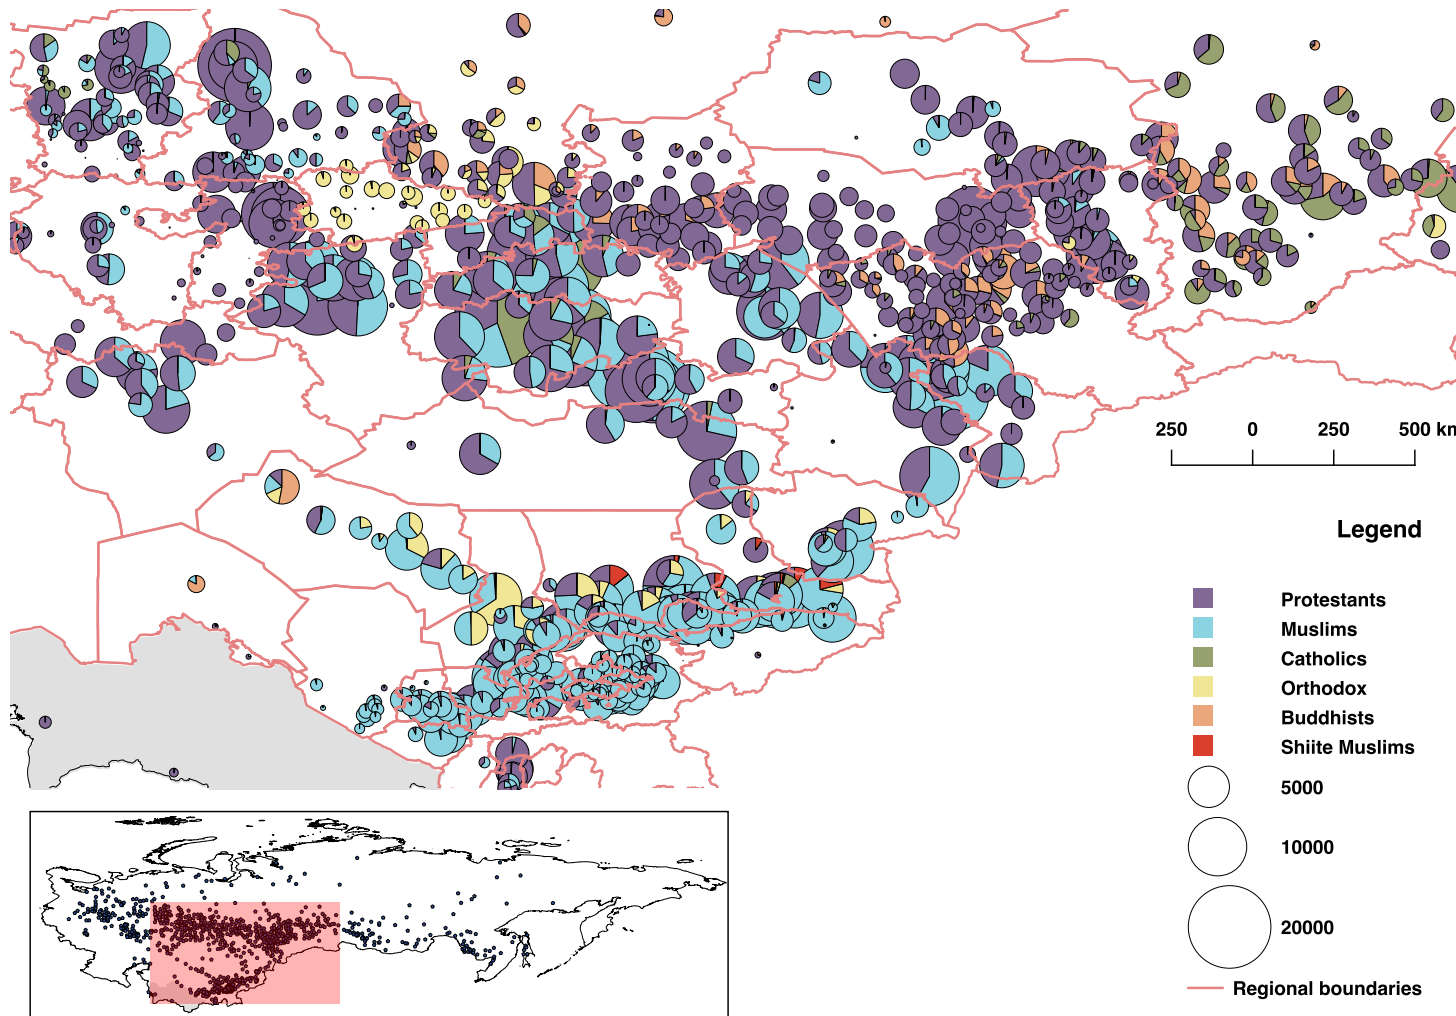

Note: The map zooms into the area with the most sizable ethnic deportations. It presents the size and the religious composition of ethnic deportations and regional boundaries.

Figure A4: Literacy gap did not decrease with literacy level across the Russian empire provinces within ethnic groups

(a)

Urban areas, all groups
Conditional scatterplot across provices and ethnicities
controling for ethnicity dummies

coef = −.03543626, se = .06931342, t = −.51

(b)

Rural areas, all groups
Conditional scatterplot across provices and ethnicities
controling for ethnicity dummies

coef = .19061088, se = .05467998, t = 3.49

Note: The figure presents scatterplots of the estimated literacy gender gap for Chechens, Germans, Russians and Central Asian ethnicities (similar to Table A2) as a function of the male literacy rate across provinces conditional on ethnicity fixed effects. Figures (a) and (b) presents the results for urban and rural areas, respectively. The sample is restricted to provinces with at least 200 individuals in each ethnicity. The figure shows that, if anything, men-women gap in literacy increases with an increase in male literacy rate.

Figure A5: Check on the deportations data, subnational-region level

Panel A: 1951 Deportation census vs. 1946 Deportation census
Protestant deportees (left) and Muslim deportees (right)

R−squared: .88

R−squared: .86
Panel B: 1951 Deportation census vs. 1970 USSR Census
### Deportee groups in 1951 excluding Chechens who left in the 1960s vs.
people of the same ethnicities as of 1970
Protestants (left) and Muslims (right)

R−squared: .74

R−squared: .99
Note: Panel A presents scatter plots of the size of the deported groups by region in 1946 and 1951 NKVD Deportation censuses, separately for Protestant and Muslim deportees. Panel B presents scatter plots of the size of the deported groups by region in the 1970 Soviet Census plotted against the size of Protestant and Muslim deportations by region in the 1951 NKVD Deportation census. In Panel B, the group of Muslim deportees excludes Chechens because the majority of Chechen deportees left the deportation locations by 1970. The unit of measurement is 1,000 people.

63

Figure A6: Variation in the share of Protestant and Muslim deportees, PSU level

Shares of Protestant and Muslim deportees
Variation across LiTs PSUs
PSUs that had an ethnic deportation, five countries
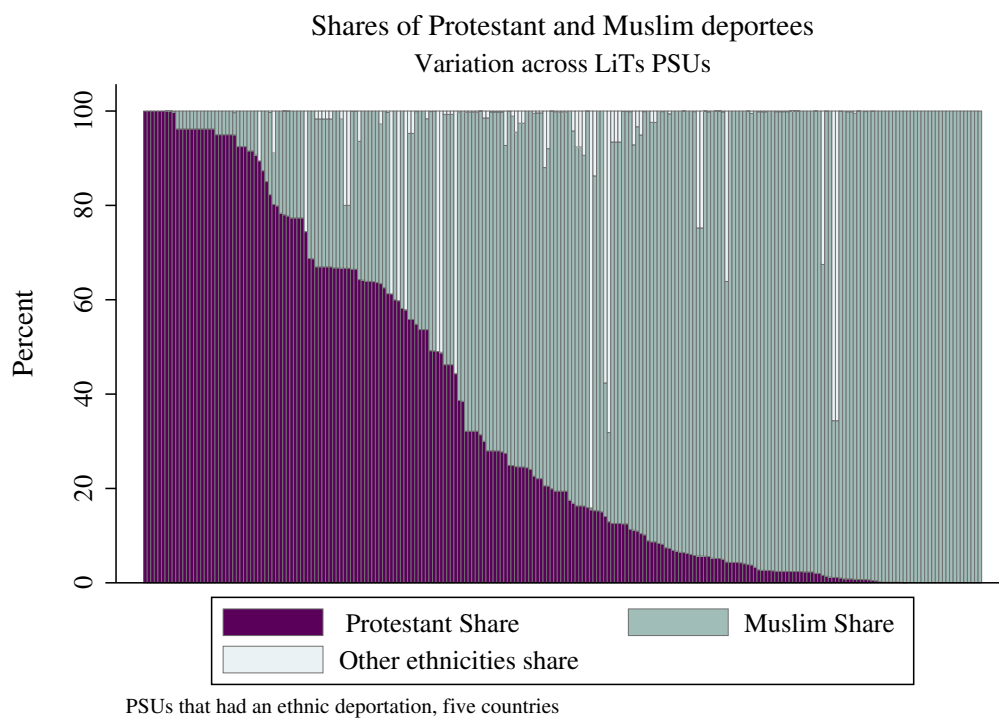

Note: The figure presents the composition of ethnic deportees across PSUs with an ethnic deportation in their vicinity. The PSUs are in the five deportation destination countries covered by the LiTS 2016 survey: Kazakhstan, Kyrgyzstan, Russia, Tajikistan, and Uzbekistan.

64

Figure A7: Variation in the number and share of Protestant and Muslim deportees among individuals living in PSUs in the vicinity of a deportation

Panel A: Number of Protestant deportees and of Muslim deportees

The distributions of the number of Protestant and of Muslim deportees for respondents in our sample
Panel B: Share of Protestant and Muslim deportees among all deportees

The distributions of the share of Protestants and of Muslims among ethnic deporteees for respondents in our sample

Note: The figure in Panel A presents the distribution of the number of Protestant deportees and of Muslim deportees among respondents of the majority group in each country living in PSUs within a 30km radius to a Protestant or Muslim deportation, respectively. The figure in Panel B presents the distribution of the share of Protestant and of Muslim deportees among all deportees for respondents of the majority group in each country living in PSUs within a 30km radius to an ethnic deportation. The distributions are estimated using an Epanechnikov kernel density function.

65

Figure A8: Variation in deportations relative to the local population in 1939

The distribution of the ratio of the number of deportees
to the 1939 district population across PSUs

Mean ratio of Protestant and Muslim deportees to the local pop is 0.2497.
(Two PSUs, with a value of 2.59 and of 3.82, are not shown.)
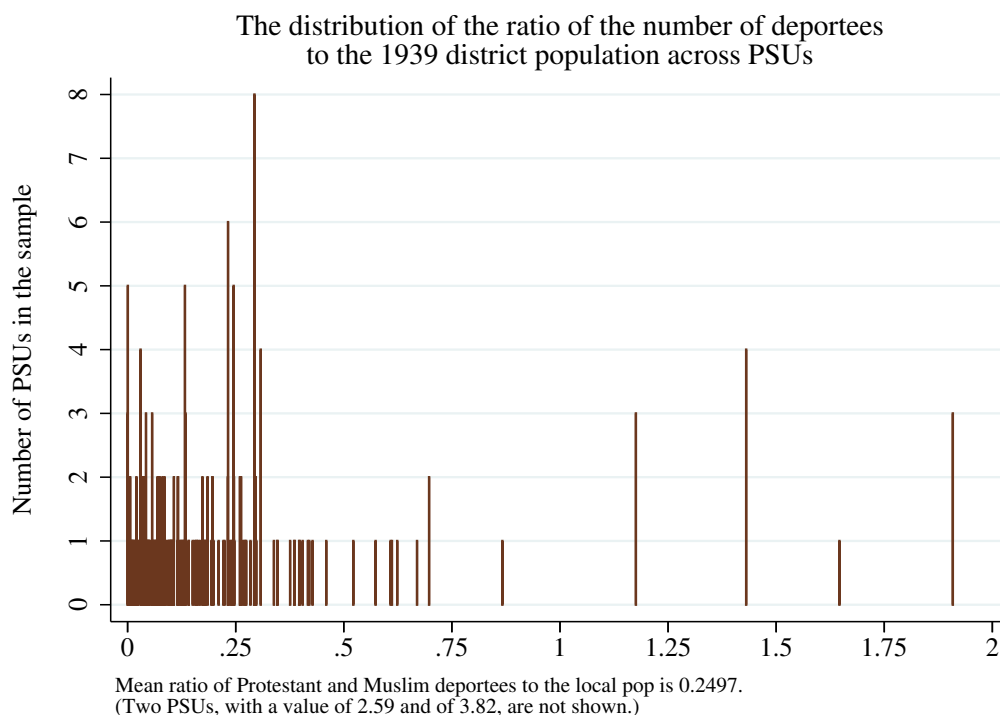

Note: The figure presents the distribution of the ratio of Protestant and Sunni Muslim deportees to the pre-war population in 1939. The sample is restricted to PSUs within a 30km radius to a deportation. Two PSUs, one with a value of 2.59 and one with a value of 3.82, are excluded from the graph. The distributions represent the number of PSUs in the sample at each value of the ratio. Data for the local population is taken from the 1939 population census. LiTS PSUs are matched to the nearest district in the census.

66

**Figure A9:** Deportation destinations and railroads
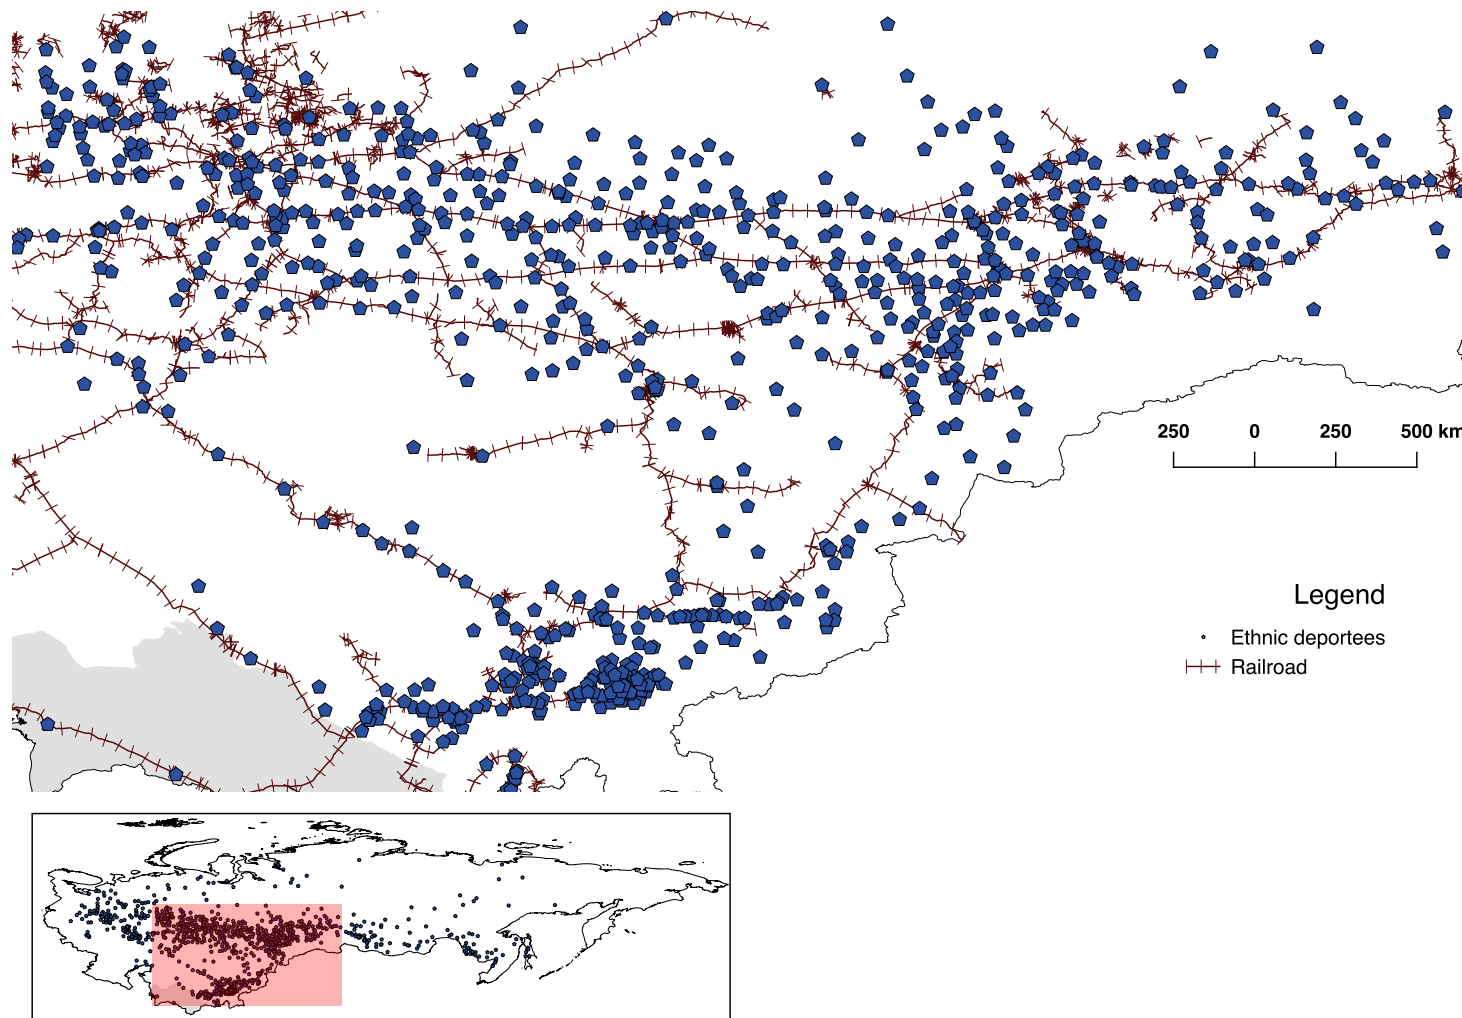

Note: The map zooms into the area with the most sizable ethnic deportations. It shows the location of deportation destinations and the railroad network.

Figure A10: The effect of the size of Protestant and Muslim deportations, by cohort

**(a)** The effect on mother's tertiary education
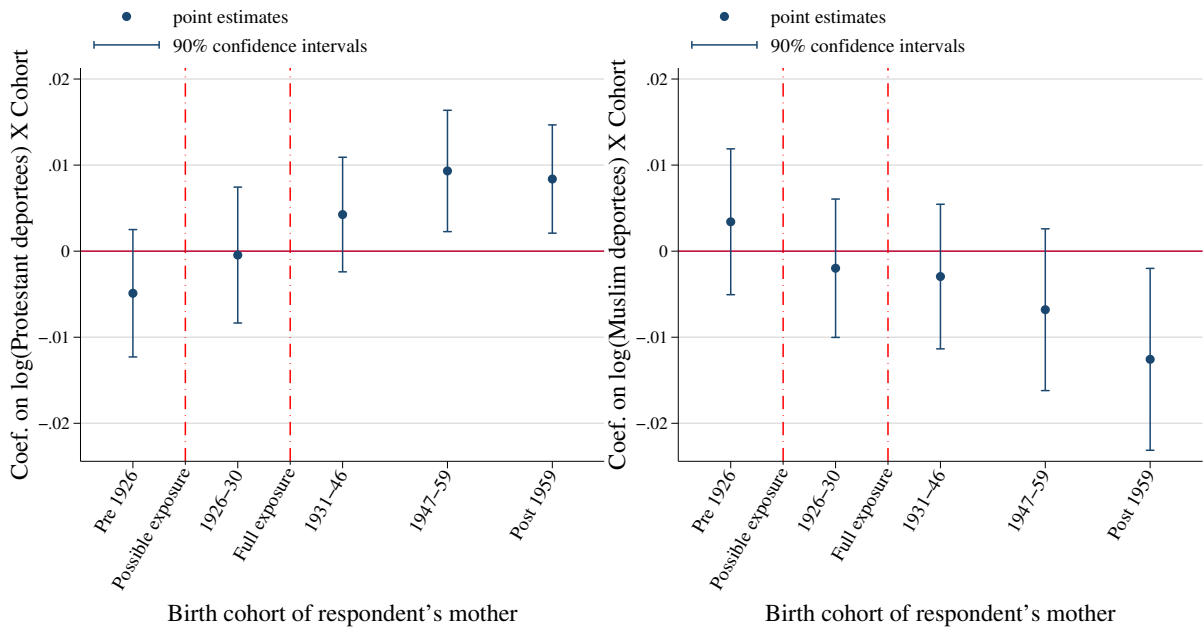

(b) The effect on respondent's gender attitudes

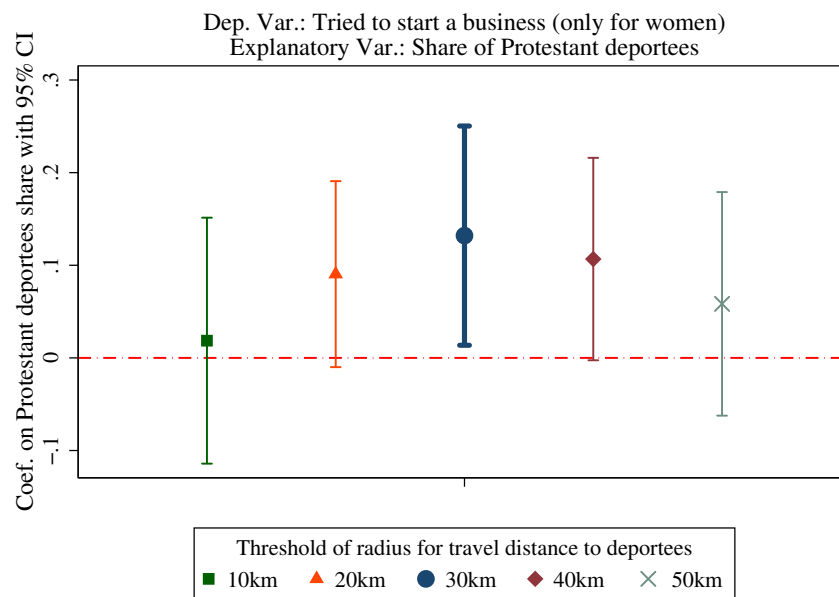

Note: Panel A presents the effect of the size of Protestant deportees and Muslim deportees on the tertiary education of mothers of respondents by mother's predicted birth cohort. Panel B presents the effect of the size of Protestant deportees and Muslim deportees on the 1st Principal Component of progressive gender attitudes, by birth cohort of respondent. There is a one-to-one correspondence between birth cohorts of respondents and birth cohorts of the mothers. The coefficients and 90% confidence intervals displayed are from the OLS regressions described in the text. Individual and destination location controls as well as cohort-group fixed effects are included. Standard errors are corrected for potential spatial correlation within a radius of 150km following Conley (1999). The two vertical lines on Panels A and B mark three groups of respondents' mothers: 1) those with no exposure (i.e., respondents' mothers who finished secondary school before deportations occurred); 2) possible exposure (i.e., mothers who were about to finish secondary school at the time of deportations) and 3) full exposure (i.e., mother who went to school after the deportations took place).

Figure A11: Robustness of the effect of the share of Protestant deportees to using different thresholds for travel distance to deportees

(a) The effect on gender attitudes

Dep. Var.: Progressive gender norms, 1st PC
Explanatory Var.: Share of Protestant deportees

(b) The effect on entrepreneurship among women

Dep. Var.: Tried to start a business (only for women)
Explanatory Var.: Share of Protestant deportees

Note: The figure presents the effect of the share of Protestant deportees on on the 1st Principal Component of progressive gender attitudes (Panel A), separately for males and females, and on a dummy for having tried to start a business, among female respondents (Panel B).The coefficients and 95% confidence intervals displayed are from OLS regressions that control for the share of all other deportee groups (excluding Sunni Muslims) and the total size of deportations at various distance thresholds (N=10km, 20km, 30km, 40km or 50km). The sample is restricted to representatives of the majority group in each country residing in a PSU within N km of a deportation. In both panels, all regressions are conditional on religious group dummies and region fixed effects. The regressions also include a set of individual controls (age, education and log of income) and geographic controls (log of 1939 population, distance to the closest railroad, capital city, water, and Gulag camp, past/current capital and current urban status, ruggedness, soil suitability for high and low inputs, and average long-run precipitation and temperature in summer and winter). Standard errors are corrected for spatial correlation within a 150km radius following Conley (1999).
Figure A12: Robustness of the effect of the number of Protestant and Muslim deportees to using different thresholds for travel distance to deportees

(a) The effect on gender attitudes of Protestant deportees

(b) The effect on gender attitudes of Muslim deportees

(c) The effect on entrepreneurship among women of Protestant and Muslim deportees

Note: The figure presents the effect of the level of Protestant deportees and Muslim deportees on the 1st Principal Component of progressive gender attitudes (Panels A and B), separately for males and females, and on a dummy for having tried to start a business, among female respondents (Panel C). The coefficients and 95% confidence intervals displayed are from OLS regressions that control for the size of all other deportee groups and a dummy for a Protestant or Muslim deportation at various distance thresholds (N=10km, 20km, 30km, 40km or 50km). The sample is restricted to representatives of the majority group in each country residing in a PSU within N km of a deportation. All regressions are conditional on religious group dummies and region fixed effects. The regressions also control for a set of individual controls (age, education and log of income) and geographic controls (log of 1939 population, distance to the closest railroad, capital city, water, and Gulag camp, past/current capital and current urban status, ruggedness, soil suitability for high and low inputs, and average long-run precipitation and temperature in summer and winter). Standard errors are corrected for spatial correlation within a 150km radius following Conley (1999).
